ACKNOWLEDGEMENTS

The authors would like to thank the members of Commission for Environmental Cooperation Renewable Energy Expert Committee for their contribution to the initial outline and design of this paper, and their subsequent comments on earlier drafts. In particular, we would like to acknowledge the contribution of Odón de Buen, Chantal Line Carpentier, Louise Comeau, Pierre Deschamps, Gilles Favreau, Ed Holt, Jorge Huacuz, Florian Laberge, Michel Lesueur, Joanne McKenna, Brian Moghadam, Mary Pattenden, Philip Raphals, Leslie-Ann Robertson, Helen Ryan and Blair Swezey for their expert comment.

EXECUTIVE SUMMARY

There is tremendous opportunity for renewable electricity¹ to meet an increasing proportion of the North American electricity market. This paper provides an overview of the key market demand and supply side drivers for non-large hydro renewable electricity in each of the three North American countries. The paper identifies regulatory mandates, voluntary purchases, self supply and financial incentives as the most important drivers of a renewable electricity market in North America today.

Governmental mandates refer to various legislative and regulatory laws that require the use of renewable resources (such as the renewable portfolio standard or RPS) or that may be major drivers for renewables (such as the Kyoto Protocol). Of the three countries, the United States probably has the most governmental mandates, with twenty-one states that have enacted an RPS. Canada's commitment towards action on climate change and clean air are the key governmental drivers. Canada also has a number of RPSs or RPS-like targets instituted by provincial and local governments. Even though there is no explicit, quantitative mandate for the scale-up of renewable electricity in Mexico, this is one of the priorities set forth by the current six-year energy sector strategic planning program. Government mandates are expected to drive the demand for 40,000 MW, 9,000 MW, and 642 MW of new renewable capacity by 2017 in the U.S., Canada and Mexico, respectively.

The voluntary market for renewable electricity is a demand driver in the U.S. and Canada only at this time (in Mexico voluntary consumers can opt for the self-supply scheme discussed below). In the U.S., the voluntary market has experienced exponential growth since mid-1990. This has been a result of increased availability of products, the development of new products, the decreasing price of renewables and the increased awareness of the benefits of renewable electricity. In 2004, 6.2 million MWh were sold in the voluntary market, of which almost half were to commercial, industrial and non-federal governmental customers. Altogether, voluntary purchases represented more than 2,000 MW of installed capacity. It is not unreasonable to expect that the voluntary market will support more than 7,000 MW of capacity by 2010. The Canadian voluntary market is still extremely small. Although a handful of provinces have utility green pricing programs or green marketing programs, the demand is still low right now for such products. This may be attributed partly to the current regulatory uncertainty under Kyoto and partly to the fact that most voluntary renewable purchases in Canada will be counted toward provincial and territorial targets, and therefore do not drive incremental new generation.

¹ Throughout the paper, the term "renewable electricity" is used to refer to non-large hydro-power renewable electricity generating technologies. These include wind power, solar electric, small hydro power, biomass conversion to electricity, and geothermal heat conversion to electricity. Although large hydro is clearly a renewable technology, it has been excluded on the basis that it is already commercial viable, cost-effective and well-established... Unlike large hydro, other renewable electricity technologies are not yet competitively viable in all three of the countries, and still rely on government policy drivers to a large extent. Other renewable energy applications, such as biofuels, solar thermal or geothermal heating and cooling, are outside the scope of this paper.

Federal procurement of renewable electricity can also be an important demand driver in North America. The combined total of Canadian and U.S. Federal government procurement is estimated to be 2,850,000 MWh/year. Mexico does not currently have a federal renewable electricity procurement program. All three countries may benefit from the North American Green Purchasing Initiative (NAGPI) led by the Commission for Environmental Cooperation to advance environmentally preferable government procurement programs in North America. The initiative will provide tools and information to encourage institutions, including governments at all levels, universities, hospitals, and private companies, to increase their purchase of renewable electricity, including on-site generation.

The paper then looked at supply-side drivers in each of the three countries. In Canada, there is an attractive array of incentive programs for new non-large hydro renewable projects at both the federal and provincial level. These include: accelerated tax depreciation, production incentives, research, development and demonstration programs, a Climate Fund to purchase domestic emission reduction credits, and several provincial investment funds. Similarly, the U.S. has a number of federal and state programs to support renewable development, the most significant being the federal Production Tax Credit and state Clean Energy Funds. In Mexico, the most significant supply drivers for renewable electricity are the accelerated depreciation allowance for renewable energy investments, and the Clean Development Mechanism.

The paper found that the major supply side drivers for on-site generation are net-metering, standardized interconnection rules and financial incentives. Most policies and programs to encourage on-site distributed generation in Canada are on the provincial level. They include eliminating the sales tax on small renewable energy equipment, net metering laws such as those in Ontario and Manitoba, and streamlined interconnection standards. Likewise, in the U.S., net-metering laws and federal efforts to develop universal interconnection standards have been important to the growth of on-site distributed generation. In the U.S. state funds have played a critical role in helping to bring down the costs of installed distributed generation.

In Mexico, on-site or off-site self-supply is an important component of Mexico's renewable portfolio. Because the current regulatory and legal framework supports the development of self-supply projects, it has been more successful as compared to other models for renewable development in Mexico. Future large-scale grid-connected self-supply is expected to contribute 1,000 MW of new installed capacity in coming years and is benefiting from a new interconnection agreement developed by the Energy Regulatory Commission (CRE). Small-scale grid connected self-supply has good future potential in Mexico, but more work needs to be done to enable interconnection with the grid. Off-grid self-supply is mainly driven by the demand of governmental programs, often with the financial assistance from bilateral or multilateral cooperation agencies. There is also good future potential for increased off-grid self-supply in Mexico to electrify remote and under-served populations.

Notwithstanding these achievements and positive trends, there is still room for improvement. Effective public policies supporting renewables need to be more widely implemented and lessons-learned about programs that worked or didn't work need to be more widely disseminated. More effort needs to be made to bring non-large hydro renewables on par with

non-renewable generators in terms of subsidies, tax incentives and other favorable government financing policies. Consumer understanding of the value of renewable electricity and their green pricing options is woefully low, and voluntary markets for renewable electricity are still in their infancy in all three countries. Finally, uncertainty around future carbon policies and the role of renewables in the carbon market has stymied some renewable opportunities, particularly in Canada.

In Mexico, the legal framework of the energy sector has become one of the greatest barriers to more renewable development. However, a growing consensus has emerged among a range of stakeholders about the need to foster renewable energy. Consequently, a renewable energy bill (“LAFRE”) and other bills have been proposed in Congress that would create a Renewable Energy Fund, require an increased amount of renewable electricity in the utilities’ portfolio, pave the way for a voluntary green power market, and institute a number of other measures that would facilitate more renewable development by the State-owned utilities, independent power producers and self-suppliers. The passage and subsequent appropriation needed to implement these proposed laws is still a looming question in Mexico.

To foster the continued growth of a North American renewable electricity market, the authors identify a number of opportunities where advancements would help achieve growth.

Canada

The overall recommendation for Canada is the development of a comprehensive renewable electricity vision and strategy through federal-provincial-territorial cooperation and stakeholder participation. The specific recommendations for Canada include:

Financial Incentives

- Adjust tax policies for development expense write-offs and depreciation of project assets;
- Develop market incentive programs in support of voluntary renewable markets and private sector renewable investments;
- Evaluate recently established funds that support renewable development to identify gaps and establish supplemental financial support through public benefit fees, pension funds or other financial sources;
- Develop models for First Nations’ ownership of renewable electricity facilities including possible joint venture opportunities.

Integration of Renewables into Utility Resource Planning

- Encourage an integrated approach to electricity resource planning and procurement that includes consideration of sustainable development including environmental and social externalities;
- Encourage continuous evaluation and updates of national, provincial/territorial and municipal targets to reflect the benefits identified in integrated resource planning and research, development and demonstration activities listed above.

Engaging Canadians

- Develop comprehensive regional public education and outreach programs to inform the public about provincial/territorial and municipal renewable electricity targets, benefits and options available to individual consumers;
- Undertake regional surveys and interpretive polling strategies to inform the public about the benefits of renewable electricity and to help suppliers hone their message to attract consumers;
- Undertake a targeted campaign aimed at companies that have a corporate mission statement that is compatible with a renewable purchase. Target multi-national companies that are purchasing renewables/renewable certificates as potential early participants in the program and support their use of “Made with Renewable Electricity” or similar public recognition labels;
- Support First Nations and remote communities’ engagement in the renewable market.

Improve the Infrastructure for Renewables

- Implement a proactive and integrated approach to transmission planning and grid expansion that incorporates provincial/territorial and municipal renewable electricity targets;
- Develop recommendations concerning funding transmission line extensions and upgrades, including reasonable cost sharing by developers, utilities, consumers or governments in public-private partnerships;
- Use regional study groups to evaluate grid integration and coordination issues;
- Develop a Federal/Provincial Best Practices Handbook on Integration of Intermittent and Non-intermittent Renewable Resources into the Electricity Grid based on international experience.

Integration of Renewable Electricity into Local Planning and Permitting

- Develop streamlined models for zoning standards and clarification of land use policies to support renewable electricity targets;
- Develop “one stop shopping” model for the processing of planning applications at provincial levels;
- Develop a handbook on best practices for planning and permitting renewable electricity to use in training of local officials and other relevant persons;
- Streamline environmental impact assessments for renewable electricity projects tailored to the needs of specific technologies and harmonized among jurisdictions so that one process offers federal and provincial/territorial approvals;
- Assist First Nations in community energy planning.

Incorporate More Distributed Generation into the Supply Mix

- Refine net metering programs and interconnection standards where they exist and support their creation where they do not already exist;
- Develop a commonly agreed-upon method for measurement and verification of the output from smaller distributed generation projects so they can be incorporated into renewable certificate program sales;
- Develop a mechanism for issuing and tracking renewable certificates from such projects;

- Incorporate distributed renewable generation into national and provincial targets and support these targets with some type of capital buy-down or other type of incentive program; and
- Develop incentive programs for renewable electricity generation in remote communities so it is competitive with subsidized fuels (such as diesel) used in electricity generation.

United States

For the U.S., the country specific recommendations include:

Advancing Industrial, Commercial, and Institutional Procurement

- Help advance the creation of a national certificate tracking network across the U.S. so that large buyers can feel confident of the renewable certificate purchases;
- Expand the deployment of renewable electricity technologies and purchases of electricity or renewable certificates at federal, state and local government sites through the CEC's North American Green Procurement Initiative;
- Increase federal and state support for and involvement in renewable electricity outreach activities.

Financial Incentives

- Extend the PTC "placed-in-service" period from two years to a timeframe consistent with project development requirements, from 2007 to 2015;
- Develop a federal program that allows the tax credits from the PTC to be traded and transferred, so that their value can be more readily monetized;
- Develop a federal program to allow use of tax-exempt bonds for private developers of renewable electricity projects;
- Increase funds available at the state and federal level to increase incentives for renewable distributed generation and supporting renewable industry and infrastructure development.

Maintaining Effective State RPS Programs

- Support best practice policies that discourage state RPS programs from allowing voluntary renewable electricity purchases, either under a green marketing or green pricing scheme, to count towards their RPS target;
- Encourage states to adopt output-based cap and trade programs where generators get a pro rata share of allowances or encourage states to provide adequate set-asides for renewables sold in voluntary markets.

Expanding Public Understanding of Renewable Electricity Beyond the Environment

- Develop materials that promote the benefits of renewables beyond their environmental value; and
- Encourage the use of renewables as a financial hedge against volatile fuel prices.

Mexico

The country specific recommendations for Mexico, which will largely be achieved through the passage of the LAFRE bill, include:

Opportunities in CFE's Expansion Planning Process

- Give an explicit mandate to the State-owned utilities to include renewable electricity in its expansion planning, as well as quantitative targets;
- Provide financial incentives for projects that deliver renewable electricity to the utilities, thereby compensating the positive externalities;
- Recognize the capacity contribution of intermittent renewable energy sources - notably wind;
- Favor small producer (under 30 MW) projects in two ways: (i) by giving the State-owned utilities the mandate to include some small projects in their expansion planning; (ii) by providing incentives to projects not included in the utilities' planning (thereby offering a supply driver for these projects);
- Review the methodology for determining the fossil fuel price forecasts.

Opportunities in Green Pricing Schemes

- Create green tariffs with a long-term stability guarantee.

Supply-Side Opportunities to Increase Grid-Connected Renewable Electricity in Mexico

- Consider redirecting any electricity premiums paid by the federal government toward the purchase of renewable electricity;
- Provide financial support for the assessment of the potential of renewable energy sources nationwide, thereby overcoming the lack of information barrier for all renewable electricity projects;
- Address public awareness, public participation and social responsibility, thereby contributing to foster social acceptance of renewable electricity projects.
- Promote administrative simplification and coordination by the federal, state and municipal authorities, in order to facilitate the procurement of the required licenses for new projects;
- Undertake awareness raising activities in resource-rich areas.

Opportunities to Increase on-Grid Self-Supply of Renewable Electricity in Mexico

- Strengthen the role of development banks in the provision of guarantees for municipalities in self-supply agreements; and
- Follow-up and replicate the experience of the Integrated Energy Services for Small Communities in Rural Mexico project.

The NAAEC Parties should be commended for their commitment to reduce the impacts of electricity generation and trade on the environment by supporting the increased deployment of renewable electricity technologies. The paper offers several recommendations for the NAAEC Parties for follow-up activities that would support a North American renewable market. These recommendations will facilitate information sharing among the three countries, and will strengthen greater joint governance and cooperation towards encouraging the deployment of more renewable energy across North America.

1. Compile best practices for power system dispatch, integration of intermittent resources, and integration of distributed resources. Foster tri-national information sharing on such best practices in a format that is most likely to be effective and useful.
2. Prepare a report that quantifies the financial value and public benefit of renewables as a hedge against fuel costs, a mechanism to increase portfolio diversity. The report would tailor its findings to two main audiences, utility integrated resource planners and large electricity users that may not fully appreciate the price stability of renewables.
3. Help advance programs that will provide recognition to commercial, industrial and institutional purchasers of renewable electricity, such as the EPA Green Power Partnership or “Made with Renewables” or similar product labeling initiatives. Support tri-national information sharing on how to best develop a buyers recognition program.
4. Develop case studies of the most successful programs for encouraging companies to either buy renewable electricity, install on-site renewable generation, or become equity owners in utility-scale generation projects. Identify the most compelling motivational factors for these electricity users. Investigate opportunities for enhancing, expanding or replicating such programs in relevant markets.
5. Help advance the development and expansion of a North American market for RECs. Help advance the development of compatible standards for REC integrity and initiatives to prevent double counting of RECs used in voluntary and mandatory markets.
6. Help advance federal government renewable electricity procurement initiatives in each of the three countries.
7. Develop a compendium of policies, examples, best-practices, and “how-to guides” for off-grid distributed renewable generation that would provide practical guidance for small groups, e.g. indigenous populations, to select, finance, and install renewable distributed generation.
8. Help advance work to update and expand user functionality of the North American Renewable Energy Directory.
9. Prepare a report on the key market demand and supply drivers for non electrical applications of renewable energy technologies.
10. Prepare a report focusing on the development, deployment and market drivers for renewable energy technologies.
11. Increase international cross-border trading of renewables between the three countries on short- and long-term markets.

SECTION I. INTRODUCTION

There is tremendous opportunity for renewable electricity² to meet an increasing proportion of the North American electricity market. Many states and provinces in the U.S. and Canada have adopted some type of renewable target creating a strong demand for renewable electricity. At the same time, there has been an upsurge in the growth of the voluntary market from large corporate and other commercial purchases, particularly in the U.S. market. Rising prices for natural gas and other fossil fuels has allowed suppliers to position renewable electricity as a hedge against fuel market volatility- demonstrating the value of renewables beyond environmental benefits. In Mexico, two new pieces of legislation will address some of the legal and market constraints on renewables if they are promulgated and private developers are finding creative ways to develop wind power projects. These and other factors show great promise for a continued growth of a renewable electricity market in North America.

Notwithstanding these achievements and positive trends, there is still room for improvement. Effective public policies supporting renewables need to be more widely implemented and lessons-learned about programs that worked or did not work need to be more widely disseminated. More effort needs to be made to bring non-large hydro renewables on par with non-renewable generators in terms of subsidies, tax incentives and other favorable government financing policies. Consumer understanding of the value of renewable electricity and their green pricing options is woefully low, and voluntary markets for renewable electricity are still in their infancy in all three countries. Finally, uncertainty around future carbon policies and the role of renewables in the carbon market has stymied some renewable opportunities, particularly in Canada.

Renewable electricity is derived from naturally regenerating energy resources such as the sun, wind, water, biomass and heat from the Earth's interior. Renewable resources can be used to produce electricity, provide heating and cooling for buildings, for industrial process heat, to provide mechanical power for grinding or water-pumping or to produce liquid biofuels. Hereafter the term "renewable electricity" will be used to refer to all renewable energy technologies for the generation of electricity, except large hydropower. Although large hydro is clearly a renewable technology, it has been excluded on the basis that it is already commercial viable, cost-effective and well-established. Unlike large hydro, other renewable electricity technologies are not yet competitively viable in all three of the countries, and still rely on government policy drivers to a large extent. Other renewable energy applications, such as biofuels, solar thermal or geothermal heating and cooling, are outside the scope of this paper but may be covered in subsequent work under the CEC.

This paper provides an overview of the key market demand and supply side drivers for non-large hydro renewable electricity in each of the three North American countries. The paper identifies

² Throughout the paper, the term "renewable electricity" is used to refer to non-large hydro-power renewable electricity generating technologies. These include wind power, solar electric, small hydro power, biomass conversion to electricity, and geothermal heat conversion to electricity. Non-electricity generating technologies, such as solar thermal applications, geothermal heating/cooling technologies and biofuels, are outside the scope of this paper.

regulatory mandates, voluntary purchases, self supply and financial incentives as the most important drivers of a renewable electricity market in North America today. We then explore the opportunities for growing the renewable electricity market in each of the three countries. This paper concludes with a series of brief recommendations for the market overall and for the Parties of the North American Agreement on Environmental Cooperation (NAAEC) specifically to help foster a North American renewable electricity future.

1.1 Current Policy Framework for Renewable Electricity in Canada

In Canada, electricity regulation occurs primarily at the provincial level. Provinces have jurisdiction over resource development, and as a result most aspects of energy policy and regulation reside with the province. Any regulatory initiatives to increase production or to set resource targets also originate with the provinces. That said, the Federal Government has on occasion ventured into energy policy, and the National Energy Board has some role with respect to exports and to inter-provincial transmission.

The structure and role of electric utilities in Canada varies by province. Most electric utilities are provincial Crown Corporations owned in total or in part by the provinces. However, there is an increasing number of private electric utilities. There is wide variation regarding utility control of the transmission and distribution system province-wide. For example, in Quebec, Saskatchewan, Manitoba, and the Maritime Provinces, a single utility is responsible for electricity distribution throughout the province. In Alberta, there are four distribution utilities, in British Columbia there are two, and in Ontario, many. Alberta has a "fully restructured" electricity system, meaning that electricity generation, distribution, and retail sales have all been separated. Ontario started down the path of restructuring and split the Crown utility into three parts, but stopped there. Thus, a very large part of the Ontario generation system is still government-owned, and most consumers are not exposed to market prices. New Brunswick, Quebec and British Columbia have adopted certain aspects of the competitive model, while retaining a Crown utility. In the other provinces, the utilities are vertically integrated, where the utility is responsible for the generation, transmission and retail distribution of electricity.

In addition to the seventeen major electric utilities in Canada, about sixty industrial establishments generate electricity, mainly for their own use. A few also sell energy to municipal distribution systems or utilities. These establishments are concentrated in three sectors: pulp and paper, mining, and aluminum smelting. In 1997, industrial establishments owned about six percent of total capacity and produced about eight percent of total electricity generated in Canada.

Green marketing is restricted to the provinces with a fully open electricity market while green pricing could be offered by any of the utilities in any market (fully open or not), though it has been limited thus far.

Though the costs of renewable power have declined significantly over the past two decades, the availability of abundant energy resources in Canada, including large hydro electric facilities, natural gas and coal, contribute to continued low prices for electricity that make it difficult for

renewable electricity to compete. As one industry representative said: “Electricity in Canada is undervalued and renewable electricity is really undervalued.” This very low electricity price is the greatest barrier to renewable electricity development in Canada.

A commitment to global action on climate change, as demonstrated by Canada’s ratification of the Kyoto Protocol, is one of the key drivers for the current incentives supporting the development of ‘new’ renewable electricity at the national level. A commitment to global action on climate change, as demonstrated by Canada’s ratification of the Kyoto Protocol, is one of the key drivers for the current incentives supporting the development of ‘new’ renewable electricity at the national level.

However, according to a recent report, the 2003 recorded greenhouse gas emissions increased twenty-four percent during the last ten years and are now thirty-two percent above the Canadian target set in the Protocol for 2008 to 2012.³ Moreover, eight-one percent of the greenhouse gas emissions come from energy production and consumption. This means that Canada has a difficult road ahead if it is to meet its greenhouse gas reduction targets.

The tentative national plans for greenhouse gas reductions do not set an absolute cap on the country’s greenhouse gas emissions but rather set a carbon intensity target that Large Emitting Facilities must try to meet.⁴ What this means is that even if the large emitters reach their carbon intensity targets, if there is growth in electricity demand, greenhouse gas emissions will continue to rise. Although this is likely to encourage some market development, it is much less of an incentive for renewable generation than if there were an absolute cap on carbon.

Often the main driver for renewable electricity development at the provincial level is air pollution as this tends to fall under provincial jurisdiction. For example, the emissions trading system in Ontario is designed to reduce NO_x and SO₂ levels and renewable electricity projects can be issued credits through a set-aside process.

Though the Canadian government has developed an attractive menu of renewable electricity incentive programs, complementing some aggressive provincial and territorial renewable electricity targets (see Section 3.2.1), still at the time of this writing, the rules and criteria for many of the programs (particularly in the Climate Change area) have not yet been finalized and there is great uncertainty concerning how the provincial and municipal targets, federal and provincial incentive programs, federal offset system and various funds will all come together. As a result, though the future for non-large hydro renewables in Canada seems positive, it is also very uncertain with regard to its size and how it will unfold. At the same time there is also considerable momentum towards increasing development of these sources.

³ Environment Canada, Statistics Canada and Health Canada updated report on greenhouse gas emissions published December 2005 and quoted in the Canadian press:

www.CTV.ca/servlet/ArticleNews/story/CTNews/20051214/Pollution_Study_051214

⁴ As long as reaching the intensity target does not cost more than \$14/ton of carbon.

1.2 Current Policy Framework for Renewable Electricity in the U.S.

The U.S. electricity market is governed by the Federal Energy Regulatory Commission (FERC) and the state public utility commissions. FERC is an independent government agency, officially organized as part of the Department of Energy. With regards to electricity markets, FERC is responsible for regulating the interstate transmission of electricity, regulating the wholesale sales of electricity, and licensing and inspecting hydroelectric projects, and monitoring energy markets and companies to protect customers from market manipulation. Individual state public utility commissions regulate retail sales of electricity, approve all utility resource plans, and generally regulate utility operations ensuring consumers and the public are protected from the possible adverse effects of a natural monopoly. More than half of the U.S. states are vertically integrated, meaning that the local utility company is responsible for the generation, distribution and retail sale of electrical energy to consumers within their service territory. Twenty-one states have “restructured” their electricity markets to allow consumers direct retail access. In general, this means that the local utility continues to provide transmission and distribution (delivery of energy) services, but consumers may choose their own supplier of generation energy services.⁵

In both restructured and regulated states, renewable generation can be procured in one of three ways: One, the utility or the retail electricity supplier can develop their own renewable generation projects. In this instance, they may either build the generation themselves or pay someone to do it for them. In either event, the utility owns the generation asset and is reimbursed for their investment through rates including a reasonable return to the shareholders. Two, the utility can buy the electricity from an independent power producer and recover the costs through rates. In this instance, the utility does not own the generation asset, but enters into longer term contracts for the delivery of the electricity into their service territory. Third, the utility may purchase RECs and combine them at the point of sale to “green-up” their system power mix.

Although a renewable portfolio standard (RPS) passed the U.S. Senate three times in the last four years, there is very little renewable electricity policy activity in the U.S. at the Federal level with two exceptions, the Production Tax Credit (PTC) and the Energy Policy Act of 2005 (EPACT 2005). The PTC has been a strong Federal incentive for renewables, primarily wind, although it has not been a stable and persistent policy over the years, expiring every two years and then being reauthorized. The PTC is discussed in more detail in Section 3.2.2.1. The EPACT 2005 has a number of incentives for renewables, including the reauthorization of the PTC, the availability of up to \$800 million in clean renewable energy bonds for renewable generators, an increased business investment tax credit for solar and geothermal, and a new residential solar tax credit.

These Federal programs aside, nearly all renewable policy activity is occurring at the state level. Currently twenty-one states plus the District of Columbia have passed RPS’s, and these have

⁵ California repealed direct access, but not the restructuring legislation. The state’s local utilities are largely divested of their generation assets, yet there is no direct access for individual electricity customers. California does offer community aggregation, where an entire community can opt to purchase retail electricity services from competitive suppliers, although no communities have taken advantage of this limited form of direct access.

been some of the most significant policy drivers for new renewable resources. In addition, state clean energy funds have made significant contributions to the growth of the renewable electricity industry by providing financial programs that support new renewable projects of all sizes, as well as funding market preparation, infra-structure building activities, and demand side drivers like consumer education and marketing. States have also aggressively enacted net metering laws, voluntary green power programs, and a variety of financial incentives and regulatory provisions to encourage new renewable energy development. Overall, however, the impact of these state-level actions is still modest relative to the potential impact of more aggressive federal policy.

1.3 Current Policy Framework for Renewable Electricity in Mexico

Since 1960, in Mexico, the generation, transmission and distribution of electricity for the public service are, according to the Constitution, a power of the State, through its two vertically integrated utilities, *Comisión Federal de Electricidad* (Federal Electricity Commission or CFE) and *Luz y Fuerza del Centro* (Light and Power of the Center or LyFC)⁶. Energy policy is dictated by the Federal government with virtually no state-level involvement. In addition, on account of amendments introduced in 1992, the Public Electricity Service Act (LSPEE) allows the participation of the private sector in the generation of electricity (Ley del Servicio Público de Energía Eléctrica, 1993), regulated by the *Comisión Reguladora de Energía* (Energy Regulatory Commission or CRE).

In this framework, electricity generation projects in Mexico can fall into four different categories:

1. The projects included in CFE's expansion planning. These in turn can be:
 - Utility-owned projects. In the past CFE used to build its own projects, but now it prefers turn-key projects, financed and built by the private sector, and then handed over to CFE.
 - Privately-owned projects built for public service. An increasing capacity in Mexico is based on independent power producers (IPP) that generate electricity for exclusive sale to CFE. (Currently there are no renewable electricity IPP projects in operation).
2. Privately-owned power export projects. (Currently there are no renewable electricity export projects).
3. Grid-connected self-supply projects. Since the LSPEE Act prevents the trade of electricity, all partners of a self-supply project need to constitute a single entity, and therefore the exchange of electricity is an internal transaction. According to the regulatory framework, self-supply projects can be either on-site or remote (by means of the wheeling services of the grid).
4. Off-grid projects. These in turn can be:

⁶ LyFC covers the Federal District and the surrounding region in central Mexico, while CFE covers the rest of the country. CFE is in charge of 97% of the total generation capacity in Mexico (excluding self-supply) and provides electricity to meet most of the electricity needs of LyFC. Although in practice CFE is responsible for contracting virtually all new public sector capacity in Mexico (with the exception of a set of natural gas-based distributed generation plants that LyFC will soon install), any reference to CFE in this document applies in principle to LyFC as well.

- Private mini-grids. In this case the same self-supply rules apply, i.e., consumers must be partners of the project.
- Home systems. Likewise, since the trading of electricity is not permitted, the consumer must own or co-own the generating device.

In addition, the LSPEE Law establishes a fifth category of projects: Small producers (under 30 MW) that generate electricity exclusively for CFE (public service) but are not included in its expansion planning. This category does not exist in practice, since the tariffs paid by CFE (short-term marginal cost and no capacity payment) are too low to enable the projects' financial viability.

1.4 Electricity Generation in North America

The graphs below show the current electricity generation mix in Canada, the U.S. and Mexico, and the tables show the installed capacity of non-large hydro power renewable electricity generation in each country.

SECTION II. CURRENT RENEWABLE ELECTRICITY MARKET DEMAND DRIVERS

The purpose of sections II and III is to give the reader a solid understanding of the current size and projected growth of the green power market in North America. The analysis will focus on both demand (Section II) and supply (Section III) drivers in each of the three countries.

2.1 Regulatory Drivers: Renewable Portfolio Standards and Greenhouse Gas Initiatives

Regulatory drivers refer to various governmental and regulatory laws, regulations and other initiatives that require the use of renewable resources (such as RPS) or that may be major drivers for renewables (such as the Kyoto Protocol). An RPS is a public policy tool that establishes a target quantity of renewable electricity to be included in an electric service provider's portfolio by a certain date. RPS can be implemented in a number of different ways, and as with most public policies, the design of the program is critical to its success.

Of the three countries, the United States probably has the most governmental mandates, particularly at the state and local levels while Mexico has the least. Canada, as a signatory of the Kyoto Protocol Annex I has its Kyoto target as a key governmental driver but also has a number of RPS's or RPS-like targets instituted by provincial and local governments.

The following section describes the governmental mandates of each country and attempts to estimate the size of the market for renewables that might result.

2.1.1 Canada

2.1.1.1 The Kyoto Protocol

Canada is a signatory of the Kyoto Protocol and as such is in the process of developing the rules and regulations that will be used to reach its greenhouse gas reduction targets. To the extent that renewable electricity does not produce greenhouse gases and is brought into the electricity supply mix to replace existing or potentially polluting fossil generation, renewables can become an important Kyoto compliance tool for Canada's electricity sector.

If Canada's electricity market proceeds as other countries have, we can expect a significant portion of Canada's non-large hydro renewable electricity projects to be built and financed by independent power producers (though mostly through long-term contracts with the utilities). Whether all the kWhs of renewables generated in Canada will be counted toward meeting the Kyoto targets or whether some renewable electricity will to be sold in a province or exported to the U.S. will ultimately be determined by the Kyoto implementation rules,

which may have significant impact on the renewable market.⁷ Certainly there is likely to be a Canadian market for carbon benefits from CDM projects located in Mexico. The extent of that market and the likely prices to be paid will depend upon what the cost and availability is of other options both from within Canada as well as from other developing countries.

Climate Change Plan – Key Components⁸

The following is a list of the key in-country components of Canada's Climate Change Plan as it is currently proposed:

- Partnership Fund -- Collaborative with provinces & territories
- Large Final Emitters (LFE) System – Greenhouse gas emission intensity constraints and emissions trading, covering fifty-five percent of Canadian emissions.
- “Climate Fund” – Canada Emission Reduction Incentives Agency
- Offset Credit System (for detail see below)
- Other Programs – Wind Power Production Incentive (4,000 MW by 2010); Renewable Power Production Incentive (1,500 MW by 2010); and Green Power Procurement (twenty percent of federal electricity usage as well as other voluntary renewable electricity markets) – see details in the section on financial drivers.
- Market Incentive Program

Renewable facilities can acquire registered offsets, to the extent they are eligible (see below), and then can sell those offsets to LFEs to reduce their greenhouse gas emission intensity, to provincial or municipal governments, to the Climate Fund, or other buyers in the US or international markets. The other incentive programs primarily reduce the cost for various governmental and utility players to purchase renewables.

Offset System: This is a national voluntary program proposed under the Canadian Environmental Protection Act. The system creates domestic ‘offset credits’ and deposits them in Canadian tracking system⁹ accounts. There are no restrictions on participants in offset projects. (At the present time, no Joint Implementation (JI) projects are being hosted in Canada.) Credits are issued for reductions and removals achieved from registered offset projects started in 2000 or after, for an eight year period beginning as early as 2006. To be eligible for credits, it is proposed that the reductions or removals must meet several criteria.¹⁰

The demand for offset credits comes from LFEs, the Climate Fund (see above) and others. There are no restrictions on who can buy offset credits and they can be traded through bilateral contracts, through brokers, and private-sector trading platforms within Canada but

⁹ To be administered by Environment Canada.

¹⁰ These criteria can be found in the following document: Government of Canada. *Overview Paper and Technical Background Document*, Canada: 2005, presently out for review & comment.

cannot be traded with other Kyoto signatories for the purposes of meeting their Kyoto targets. A \$15 per ton price assurance for LFEs is likely to keep the price of offsets at or below this level. Eligible renewable electricity and/or renewable certificates could be bundled with offset credits for renewable electricity marketing. If so, it would be necessary to have the renewable electricity product EcoLogo-certified.

Rules for the offset market are permissive and offsets could be sold in the voluntary market or programs like the Alberta consultative market. Because the Kyoto rules and regulations are still being formed in Canada, this has inserted some amount of uncertainty as to how renewable electricity will be handled. Some utilities have moved forward in contracting for renewables, while others have taken a “wait and see” approach.

As a result, some areas of renewable development and procurement are presently on hold until there is clarification. Regulatory uncertainty is a key concern that affects reporting of greenhouse gas credits, pricing, willingness to trade, and attempts to minimize or shift various risks for all of these trading activities. For both U.S. companies trading in Canada and Canadian companies trading in the U.S., there is the further uncertainty of how and when greenhouse gas reduction requirements in Canada and the EU will affect the trade prospects given that the U.S. did not ratify the Kyoto Protocol. It is very difficult at this time to forecast the size of the Canadian renewables market that may result from Canada’s Kyoto activities particularly the potential size of the offset market since the offset market will intersect with the provincial RPS and “RPS like” targets as well as the voluntary market. In addition, the offset market will be supported by purchases by the Climate Fund, and incentive programs like the Wind Power Production Incentive (WPPI), the Renewable Power Production Incentive (RPPI), the Renewable Energy Deployment Incentive (REDI) and other federal and provincial incentive programs. Therefore, though we know there will be some additional renewables resulting from the offset program, there is no basis for assessing their volume at the present time. For the purposes of this paper, it will be assumed that the offset market will not add any additional renewables beyond what is already being calculated in the mandatory compliance markets.

2.1.1.2 Provincial Procurement and Portfolio Mandates

Three provinces have renewable electricity mandates in place in Canada as of September 2005, New Brunswick, Nova Scotia, and Prince Edward Island.¹¹ These are most likely to be fulfilled through a utility’s purchase of renewables from local facilities. However, rules could change in the future and allow for the purchase of unbundled RECs from anywhere. Most of the provincial mandates or targets are all inclusive and count any renewable power generated in the province whether sold through regular utility sales, purchased to meet government procurement mandates or purchased by end-use customers in the voluntary market.

In addition to these provincial RPS programs, seven provinces and three territories have ‘RPS like’ electricity targets. These include: Alberta, British Columbia, Manitoba,

¹¹ Pollution Probe. *Green Power Provincial/Territorial Targets and Policies*, September, 2005.

Newfoundland and Labrador, Ontario, Quebec, Saskatchewan, Yukon, Northwest Territories, and Nunavut. These targets are politically not legislatively based but are just as likely to be realized. The level of each provincial/territorial mandates and targets are shown in Figure 4.

Many of these goals are being driven by a desire for local economic development. But, to the extent that the Canadian implementation of the Kyoto Protocol puts pressure on the provinces and territories to reduce their greenhouse gas footprints, some (that do not have many renewable resources themselves) may choose to purchase renewable certificates, carbon offsets, or offsets from CDM projects as part of their compliance activities.

In provinces with traditional, vertically integrated utilities (without wholesale competition) power generated by renewables can command a premium over the prevailing wholesale market price only if those facilities are owned by independent power producers that have contracted their output through some form of power purchase agreement. The various federal government incentive programs are expected to help reduce the costs of renewables at the provincial level and support momentum toward reaching these renewable targets.

While it is technologically feasible for Canadian renewable projects to export their power to the U.S. for the purposes of meeting U.S. RPS mandates, there are only a few limited instances of this occurring. All of the U.S. states bordering or near Canada with a RPS require a physical energy delivery into the state or regional power pool in order for the generation to be eligible for the RPS. This means that the generation unit must be located such that there is a clear path of delivery from the renewable generation unit to the U.S. state or regional power pool. However, because of the sizable demand being created by Canadian provincial mandates, it appears that most new renewable projects in Canada are being used to meet the domestic compliance market instead of exporting to the U.S.

The estimated amount of renewables expected from provincial RPS programs and provincial targets is approximately 9,000 MW by 2014.

Figure 4. Canadian Renewable Electricity Standards and Targets as of September 2005

2.1.2 United States

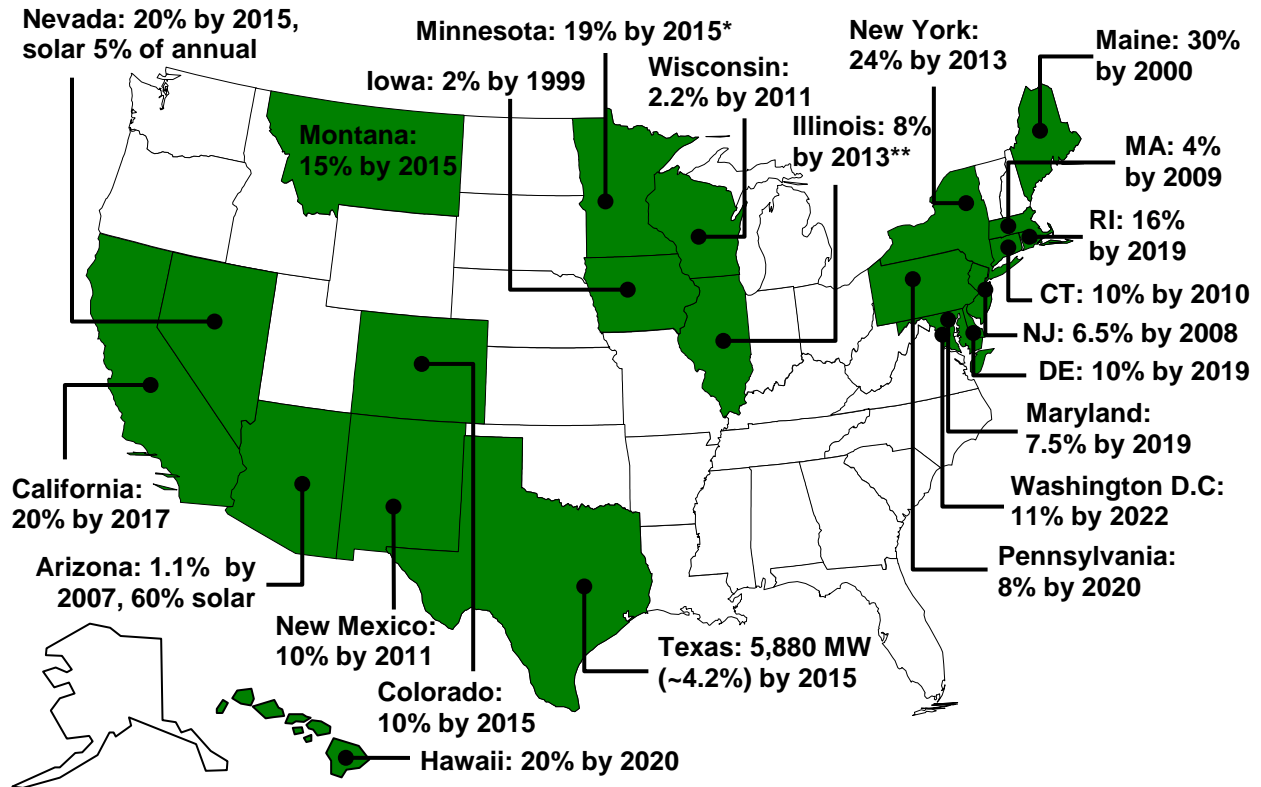

2.1.2.1 State Renewable Portfolio Standard

In the United States, the enactment of state RPS's has been a major driver in the demand for both existing and new renewable electricity, and a driver for the development of new renewable generation facilities. In general, the most successful RPS's have output-based targets (as opposed to capacity targets) that are long lasting and increase over time. Currently in the United States, there are twenty-one states plus the District of Columbia that have enacted a RPS.

The demand for renewable electricity from state RPS's is dramatic, and has been the largest boon to the renewable market in the United States since the enactment of the Public Utilities Regulatory Policy Act (PURPA) in 1978. According to the Union of Concerned Scientists, the demand for both existing and new renewable electricity from state RPS will total approximately 40,500 MW by 2017.¹² Of this amount, 32,000 MW will be from new renewable electricity.

¹² From interview and documents received from Steve Clemmer, Research Director, Union of Concerned Scientists, www.ucsusa.org.

Figure 5. United States Renewable Electricity Standards as of January 2006

Figure 6. New and Existing Renewable Electricity Demand Expected from U.S. State Standards¹³

Source: Union of Concerned Scientists, November, 2005

2.1.2.2 Federal Renewable Portfolio Standard

Although the United States has not passed a federal RPS, it bears mentioning here because of the great potential for creating demand for renewable electricity across the U.S. and because it has been included in three energy bills that have passed the U.S. Senate in the last four years. According to the Union of Concerned Scientists, the proposed ten percent by 2020 federal RPS would increase renewable power capacity by more than six times over present levels, from 17,000 Megawatts (MW) in 2003 to 109,000 MW by 2020.¹⁴

2.1.2.3 Existing and Proposed Carbon Regulation

Twenty-three states have enacted programs and policies to monitor and or reduce greenhouse gas emissions that are likely to impact the demand for renewable electricity. In an effort to normalize the widely divergent efforts we have divided the initiatives into five different categories in Table 4 below. Policies to limit greenhouse gas emissions that impact the demand for renewable electricity include, setting limits for greenhouse gas emissions from

¹³ Projected development assumes states achieve annual procurement targets.

¹⁴ Union of Concerned Scientists, "U.S. Senate 10 Percent National Renewable Electricity Standard Will Save Consumers Money, and Create Jobs." July 2005.

power plants, introducing carbon adders to utility resource planning processes, and setting targets for statewide CO₂/greenhouse gas emissions. Finally, some states now mandate reporting of greenhouse gas emissions and several have established greenhouse gas registries for voluntary action.

Greenhouse Gas Emissions Limits

Several states are undertaking efforts to set limits or target offsets for the emissions of CO₂. The efforts have primarily been targeting the power sector, but recent efforts in New Jersey and California could possibly include fossil fuel burning facilities outside of the power sector.

Massachusetts issued a rule in 2001 requiring a ten percent reduction in the CO₂ emission rates by 2006 compared to 1997-1999. The rule applies to the six highest emitting power plants in Massachusetts. The companies can apply for credits to the program resulting from investments in carbon sequestration and renewable electricity. New Hampshire established a cap on CO₂ emissions from power plants in the State in July of 2002. The law sets an annual cap for emissions in 2006 equal to CO₂ emissions in 1990. Starting in 2007 and continuing through 2010 the cap is set at a level seven percent below 1990 emissions. The law allows for the issuing of allowances for investments in energy efficiency, new renewable energy projects, conservation and load management. Oregon and Washington have implemented programs to require new power plants to offset portions (seventeen percent in Oregon, twenty percent in Washington) of their anticipated CO₂ Emissions.

Finally, seven states from the Northeastern and Mid-Atlantic regions of the United States recently agreed on a multi-state Regional Greenhouse Gas Initiative (RGGI). The states involved are Connecticut, Delaware, Maine, New Hampshire, New Jersey, New York, and Vermont. The agreed framework targets a stabilization of CO₂ emissions from the region's power plants at 2009 levels from 2010-2015 and a ten percent reduction below 2009 levels by 2019. The specific allocation of emissions allowances is to be determined state-by-state. The allowance mechanism could have a dramatic impact on the voluntary market, positively or negatively, depending on how the program is implemented in each of the states. A worse case scenario is that renewables would not be able to make any carbon claims; a best case scenario is that all renewable sales and purchases can make carbon reduction claims. In reality, the implementation is likely to be somewhere in between, where some claims can be made in limited circumstances, not altogether killing the voluntary renewable market but hurting it somewhat from today. Maryland, Massachusetts, Pennsylvania and Rhode Island are observers to the process and could join at a later time.

The question of whether greenhouse gas emission limits on the power sector encourage renewable energy depends on the specific design of the scheme and its allocation process. If greenhouse gas emitters are required to pay for the privilege of emitting carbon, then the program will increase the cost of fossil fuel generation, making it less competitive, while the price of renewable generation will remain constant. However, studies in the Northeast U.S. show that if pollution allowances are given on a free basis to the greenhouse gas emitters the value of the allowances will be worth more to the polluter than the cost of the reducing

greenhouse gases to comply with the cap.¹⁵ These issues are still being debated in the Northeast and California.

Carbon Adders

Several states have implemented versions of “carbon adders” to encourage electricity providers to take into consideration the potential future cost of mitigating carbon dioxide emissions. A carbon adder is a sum of money that is added to the procurement costs of fossil fuel generation during a utility’s resource planning process. The carbon adder explicitly takes into account the social cost of carbon emissions from electricity generation facilities when comparing prices of fossil fuel and renewable generation. California adopted a carbon adder of \$8/ton CO₂ in April of 2005. Colorado’s Public Service Commission set a carbon adder for a specific utility’s procurement plans in 2003 as part of an agreed settlement with environmental groups. The carbon adder was set at \$9/ton but it did not change the utility’s resource selection. Oregon requires that regulated utilities include an analysis of carbon costs in their resource planning. While the inclusion has not led to any changes in resource selection, it has forced utilities to include climate change as a factor affecting resource planning.¹⁶

Greenhouse Gas Targets

Several states have set targets for their future greenhouse gas emissions. Some targets are economy-wide while others are focused more specifically on the electricity sector. Some of the targets have been set by State Governors while others are bound in law. In 1998 New Jersey issued an Administrative Order targeting a three and a half percent reduction in greenhouse gas emissions by 2005 compared to 1990 levels. The State expects to surpass this goal, although the reductions have primarily been due to factors unrelated to the state’s greenhouse gas policy initiatives.¹⁷ Maine passed a law in 2003 requiring that the state reduce its greenhouse gas emissions to 1990 levels by 2010 and twenty percent below 1990 levels by 2020.¹⁸ In 2005 California’s Governor issued an Executive Order setting targets for California’s greenhouse gas emissions: “by 2010, reduce greenhouse gas emissions to 2000 levels; by 2020, reduce greenhouse gas emissions to 1990 levels; by 2050, reduce greenhouse gas emissions to eighty percent below 1990 levels.”¹⁹ Also in 2005, New Mexico’s Governor issued similar goals targeting a reduction of the State’s greenhouse gas emissions to 2000 levels by 2012, ten percent below 1990 levels by 2020 and seventy-five percent below 1990 levels by 2050.²⁰

The impact of greenhouse gas targets on the development of renewable electricity is dependent on the implementation strategies pursued by the states. In California the goal of thirty-three percent RPS is one of the main strategies envisioned in order to meet the near-term goals.

Other Greenhouse Gas Initiatives

Several states have established working groups or commissions to develop climate change plans and policies for their state, including Arizona, California, New Mexico, North Carolina, Oregon and Washington. In California, the State is considering a proposal to require mandatory greenhouse gas reporting for all large sources of greenhouse gas emissions. This is seen as a first step to a broad cap-and-trade scheme. Wisconsin has mandated CO₂ emissions reporting from all facilities that emit more than 1,000,000 tons of CO₂ per year, since 1993. New Jersey was the first state to classify carbon dioxide as a pollutant in 2005. This action is intended to strengthen the support for policies that help reduce carbon dioxide emissions. An overview of all the greenhouse gas initiatives taking place in the states can be found in Table 4, below.

2.1.3 Mexico

Even though there is no explicit, quantitative mandate for the scale-up of renewable electricity in Mexico, this is one of the priorities set forth by the current six-year energy sector strategic planning program.²¹

Despite the least-cost mandate embedded in the LSPEE Act, energy policy guidelines have enabled CFE to include renewable electricity utility-owned projects in its expansion plan. One such project is under construction: La Venta II (83.5 MW wind power).

The development of renewable resources for exclusive sale to CFE will be further encouraged by the GEF-funded Large-Scale Renewable Energy Development Project (LSREDP).²² In its first phase, due to begin in 2006, the LSREDP will provide a U.S.\$20M performance-based financial incentive (about U.S.\$11/MWh during the first five years of operation) to the La Venta III 101 MW wind project, to be bid in 2006. The LSREDP will also provide U.S.\$5M for a range of technical assistance activities aimed at facilitating the incorporation of renewable electricity into the Mexican power sector.

Unlike all previous renewable electricity CFE projects, La Venta III is a privately-owned, independent power producer. In compliance with its least-cost mandate, CFE will not pay more than its avoided cost for the electricity generated by La Venta III, and the LSREDP will cover the difference between the avoided costs and the price of the wind power.

A phase II of the LSREDP is foreseen with a further U.S. \$45M GEF grant. It seeks to support the installation of approximately 400 MW with a smaller per-MWh incentive.

With another GEF grant for U.S.\$50M, CFE will soon commission the construction of a turn-key hybrid solar/natural gas (combined cycle) power plant in the Northern state of Sonora. The concentrated solar power component will have a capacity of approximately 30 MW.

2.1.4 Summary of Cumulative Demand from Existing Mandates 2005-2016

The primary renewable electricity demand drivers in Canada are provincial and territorial measures, including RPS mandates as well as targets and RFPs for renewable energy. There is also additional impetus provided through the various climate change and clean air programs at the municipal, provincial and federal levels (including Canada's Climate Change Plan). However, at this time it is believed that any renewables that are acquired to meet provincial or territorial RPS targets will not be incremental to renewables used to meet Kyoto goals.

²¹ Secretaría de Energía, 2001.

²² World Bank, 2003.

The estimated amount of renewables expected from provincial and territorial RPS programs and targets is approximately 9,000 MW by 2014.

In the U.S., the state RPS's are currently the only significant regulatory drivers for new renewable development. The estimated demand for both new and existing renewable electricity will be approximately 40,500 MW by 2017. Of this amount, approximately 32,000 MW will be from new renewable electricity.

In Mexico the current planning foresees between 2006 and 2014 the installation of an additional capacity of 642 in wind and geothermal projects.

2.2 Voluntary Market Drivers: Green Pricing, Green Power Marketing, RECs and Voluntary Carbon Reduction

The ‘voluntary renewables market’ includes: (1) green pricing programs (renewable electricity that is offered by the utility to their customers through a special green tariff); (2) renewable electricity marketing that is offered by energy service providers in restructured electricity markets (e.g. the renewables are offered by marketers in competitive markets); (3) renewable electricity certificates that can be offered to customers in either a traditionally regulated or in restructured electricity markets. A renewable certificate represents the renewable attribute of electricity generated by a renewable resource and is sold separately from the underlying power. One renewable certificate equals the generation of one MWh of renewable electricity, but since the trading of it is not constrained by the transmission grid, it provides for a much more fluid and national market. What customers are paying for when they buy a renewable certificate is an equivalent amount of renewable electricity generation that displaces non-renewable sources from the regional or national electric grid; (4) voluntary greenhouse gas reduction programs where particularly businesses and industries voluntarily reduce their greenhouse gas footprint by buying renewable electricity, installing renewable electricity either on site or off-site (covered in the next section of this report) or by purchasing renewable certificates; and (5) other voluntary air pollutant reduction programs that might result in the purchase of electricity or renewable certificates from renewables as a pollution reduction strategy.

2.2.1 Canada

The voluntary green market in Canada is relatively small and immature, primarily due to a lack of consumer understanding and awareness about green power offerings. That said, there

are several ‘utilities’ offering renewables to their customers (primarily commercial/industrial customers): BC Hydro offers “Green Power Certificates,” to domestic commercial customers, ENMAX offers renewables through its Greenmax Program to the residents of the City of Calgary, and the Ontario Power Generation Company’s Evergreen Power is offering renewables to commercial customers. Prince Edward Island has a small green pricing program through Maritime Electric’s Green Power Program. In addition the following also have bundled renewable electricity programs: SaskPower, Toronto Hydro, Energy Ottawa, Select Power and Nova Scotia Power. There are a couple of renewable electricity programs (e.g. Energy Ottawa) that sell only to the Federal government and are included in the Government Procurement (Section 2.3) part of this report.

There are only a handful renewable electricity marketers in Canada: two are new green-power marketers in Ontario (a restructured electricity market), Select Power, and Bullfrog Power. The third, Vision Quest, sells to customers in Alberta and the United States. In addition, several groups sell renewable electricity certificates: Pembina Institute; Canadian Hydro Developers; EPCOR; Oakville Hydro; Gray Bruce Energy Co-op; Canadian Renewable Energy Corporation; and JD Irving.

Ontario has a ‘set-aside’ of tradable emission allowances for renewable electricity projects for sulfur dioxide (SO₂) and nitrogen oxides (NO_x) that has been operating since the beginning of 2002. These allowances can be sold to Ontario Power Generation (OPG), to the owners of other facilities or to other interested parties that may formally retire them. This set-aside represents a limited financial incentive to renewable projects, depending on the market value of the allowances. In order to have the intended emission reductions effects, retailers of renewable electricity and renewable certificate products in Ontario must apply for the SO₂ and NO_x allowances for the source facilities and then transfer the allowances to their customers or retire them on behalf of their customers. Otherwise unclaimed allowances will revert to OPG that can then use them to produce additional emissions. These tradable emission allowances may provide extra revenue to eligible renewable generators but they are not incremental to the Ontario provincial target.

The Environmental Choice Program, EcoLogo, reported to us that they certified 1,800 MW of Canadian owned renewables at 155 facilities in 2004.²³ However, most of this is from plants whose power is sold directly to utilities and is generally not available in the voluntary market, except in limited instances where the certificates are resold by the utility. The voluntary market for renewables in Canada today is probably less than 500,000 MWh/year and is counted as part of the provincial targets. Because of this fact, we estimate that the voluntary market will not produce any significant incremental demand for renewable electricity above and beyond the provincial targets.

²³ Personal Communication with TerraChoice.

2.2.2 United States

2.2.2.1 Voluntary Renewable Sales: Green Pricing, Green Power Marketing and RECs

Voluntary sales of renewable electricity in the United States take place in two different markets. The largest and the one that has been in existence the longest is the offering of renewable electricity by utilities and competitive electricity suppliers. For this market customers sign up with either their local utility or, if the electricity market has been deregulated, with an energy service provider (ESP) that offers a renewable electricity product. Generally, customers can choose to purchase discrete blocks (e.g. 100 kWh blocks) or a percentage (e.g. 25, 50 or 100 percent) of their electricity usage from renewable resources. In 2005 more than 600 utilities and competitive marketers offered more than 150 renewable electricity products across the United States.

The other market for renewable electricity is the market for renewable electricity certificates.²⁴ This market is of more recent status but it has experienced tremendous growth in the last few years. More than a third of the utilities which offer renewable electricity products to their customers buy renewable certificates to supply their sales.²⁵

Renewable certificates have become a preferred method of purchasing renewable energy among large national companies and organizations. In fact, most of the “Top 25” purchasing members in the EPA’s Green Power Partnership include RECs in their purchase.

Greenhouse Gas Offset Products

In 2005, several organizations began offering greenhouse gas offset products in the United States. The majority of these included renewable certificates as part of the portfolio supplied to customers.²⁶

Size of the Voluntary Market

The voluntary market for renewable electricity products has grown dramatically over the last years as seen in Table 6. Renewable electricity products provided by utilities and ESPs have grown from supplying approximately half a million MWh in 2000 to almost 4.5 million MWh in 2004. The number of customers has been increasing steadily while the sales volumes have experienced an exponential growth. This is evidence of the growing importance of purchases by businesses, government agencies and other organizations. In 2004, a fourth of the volume of electricity products sold by utilities and ESPs was bought by non-residential customers and the rest by residential customers.

²⁴ RECs are also known as “green tags” and Tradable Renewable Certificates (TRCs).

²⁵ Bird, Lori & Elizabeth Brown. *Trends in Utility Green Pricing Programs*. (Colorado: National Renewable Energy Laboratory, 2004).

²⁶ Examples of these are TerraPass (<http://www.terrapass.com>), Certified Clean Car (<http://www.certifiedcleancar.com>), and Sustainable Travel International (<http://www.sustainabletravelinternational.org>)

Table 6. Renewable Electricity Sales²⁷

		2000	2001	2002	2003	2004
Utility and ESPs	Sales (MWh)	454,000	1,532,000	2,331,000	3,180,000	4,490,000
	Customers	290,000	280,000	380,000	420,000	510,000
RECs	Sales (MWh)	-	-	150,000	600,000	1,720,000
	Customers	-	-	2,000	6,000	8,000
Total	Sales (MWh)	454,000	1,532,000	2,481,000	3,780,000	6,210,000
	Customers	290,000	280,000	380,000	430,000	520,000

The renewable certificate market is of a much more recent nature and the earliest estimates of the market size are from 2002. The volume of sales in 2002 represented the generation of 150,000 MWh, which increased to 1,720,000 MWh in 2004. Additional data confirms a rapidly expanding renewable certificate market as well.²⁸ While the market for renewable electricity is still dominated by residential customers, non-residential customers purchased more than ninety-eight percent of the renewable certificate volume in 2004.²⁹ Some of the ninety-eight percent that are sold to organizations are “repackaged” and re-sold in emerging carbon offset products. While this number is currently very small, it very likely will grow as these products gain traction.

Projections of the voluntary market are very difficult since the market can be impacted significantly by policy changes within the electricity sector as well as by regional or national policies to mitigate greenhouse gas emissions. The price of other generation sources also plays a role in determining the demand for renewable electricity products. In 2004, more than 2,000 MW of renewable generating capacity was needed to meet the demand from the voluntary market.³⁰

Market Factors

The tremendous expansion in volumes sold in the voluntary market can be tied to increases in the availability of renewable electricity products, cheaper renewable resources and recognition among businesses, government agencies and other organizations of the value of buying renewable electricity.

²⁷ The table represents a compilation of data from Bird and Swezey: *Green Power Marketing in the United States: A Status Report Eight Edition* (Colorado: National Renewable Energy Laboratory, 2005) 6-15; Center for Resource Solutions. *Verification Report Year 2000* (California, 2000) 2; Center for Resource Solutions. *Verification Report Year 2001* (California, 2002) 3; and Center for Resource Solutions. *Verification Report Year 2002* (California, 2003) 5.

²⁸ Center for Resource Solutions. *Verification Report Year 2004* (California, 2005).

²⁹ Bird and Swezey, p. 11

³⁰ Bird and Swezey, p. 17

More than half of all electricity customers in the U.S. have the option of purchasing renewable electricity from their power provider,³¹ and all electricity customers can purchase renewable certificates and carbon offset products, which are available nationwide. In general the longer a renewable electricity product has been offered the greater its participation rate, as it takes time for companies to spread the message about their product.³²

Several factors have made renewable electricity and renewable certificate products more affordable and more accessible. The continued advance in renewable electricity technologies have led to significant drops in the price of generating electricity from renewable resources. Because of the lower costs for acquiring resources, more companies are willing to offer renewable electricity products to their customers. There have also been changes to the way that renewable products are priced that has attracted corporations to buying and/or installing renewable electricity. The fact that the price of renewable electricity is not dependent on fuel supplies has attracted corporations that are concerned about volatile energy costs. This is discussed in more depth in Section 2.4. Corporations are also increasingly focused on their direct and indirect greenhouse gas emissions and view the procurement of renewable electricity as an efficient and relatively inexpensive way of reducing their greenhouse gas footprint. Finally, companies are increasingly marketing their commitment to renewable electricity by labeling their products with “Made with Renewables” and similar branding in order to differentiate their products in the marketplace.³³

A couple of other factors that have been important in supporting the growth of the voluntary market are related to the reliability and transparency of the market. Independent certification of renewable electricity products, especially in the case of renewable certificates, provides certainty to a market that is not regulated by any government.³⁴ Regional tracking systems have been established and several more are under development in the United States adding to the transparency and integrity of the market. Finally, it is important that customers are clearly informed about what they are purchasing and that the competing products are somewhat comparable. There are regional variances in what is considered renewable often as a consequence of specific state legislation unrelated to the voluntary market. Lately organizations such as the Center for Resource Solutions’ Green-e Program and the U.S. EPA Green Power Partnership have worked to develop national standards for renewable products.

A related issue is the ability for renewable suppliers to make air quality benefit claims when marketing their products. While cap-and-trade schemes for NO_x and SO₂ have either eliminated or severely limited the renewable generators’ ability to make claims about these pollutants, no such scheme has been implemented for greenhouse gas emissions, though this may change soon. Several states are working towards carbon cap-and-trade schemes (see Section 2.1.2.3) and unless renewables are granted allowances, these policies could work to undermine the voluntary renewable market. Under the Federal SO₂ cap and trade program

³¹ Bird and Swezey, p. 17

³² Wisner, Olson, Bird and Swezey, p. 24

³³ Center for Resource Solutions 2005

³⁴ World Resources Institute 2004, p. 6-7.

and most regional NO_x cap and trade programs in the U.S., emitters are given allowances under the cap. The only way a project can reduce the total quantity of a pollutant emitted in this type of program is to retire allowances. If a new renewable project comes on-line, and as a result a fossil power plant reduces their operations and thus their emissions, the power plant is then free to sell their excess emission allowances to another emitter. Thus the new renewable project has no impact in the overall amount of emissions under the cap. There are a few exceptions to this rule, where renewable projects are granted allowance set-asides, but these instances are very limited. This impacts the voluntary renewable electricity market because marketers can not make any claims with regards to reducing capped pollutants. The ability to advertise and show the air quality benefits of renewable electricity is an important sales and marketing strategy in the U.S.

2.2.2.2 Voluntary Carbon Reduction Measures: Greenhouse Gas Registries

California, Maine, New Hampshire and Wisconsin have established voluntary greenhouse gas registries. Wisconsin's registry is for more than just greenhouse gases and the State is currently involved in establishing a more regional registry involving the States of Illinois, Indiana, Michigan and Ohio. The U.S. EPA and the Department of Energy have also established registry programs. All of these registries have primarily been focused on inventorying current greenhouse gas emissions. As the registries move towards broader participation, the focus will probably shift more towards how to reduce greenhouse gas emissions. Whether purchases of renewable electricity and renewable certificates will be included as one option to reduce emissions depends on the design of their specific protocols. Since several companies that are currently participating in registry efforts are also major purchasers of renewables, it is likely that registries could adopt rules which include and thereby promote the renewable market.

2.2.3 Mexico

Currently, there is no green pricing scheme in Mexico. However, companies willing to get renewable electricity can generate electricity either on-site or remotely, via the self-supply model (discussed in Section 3.1.3.1.)

A survey made with the largest electricity consumers in Mexico shows that a green pricing scheme would likely be successful. According to the results of this survey, commissioned by the National Commission for Energy Efficiency (*Comisión Nacional para el Ahorro de Energía*, CONAE) and funded by the Commission for Environmental Cooperation, 54 out of the 100 largest consumers would be ready to pay a premium tariff for renewable electricity.³⁵

2.2.4 Summary of Cumulative Voluntary Demand in North America

The voluntary market in Canada is extremely small and immature. Although a handful of provinces have utility green pricing programs or green marketing programs, there is little

³⁵ Comisión Nacional para el Ahorro de Energía, 2002.

demand right now for such products given the current regulatory uncertainty under Kyoto. In general, most voluntary renewable purchases in Canada will be counted toward provincial and territorial targets, and therefore, we estimate zero additional demand from voluntary markets.

The voluntary market for renewable electricity in the U.S. has experienced exponential growth in the United States since its inception in the mid-1990. This has been a result of increased availability of products, the development of new products (such as RECs), the decreasing price of renewables and the increased awareness of the benefits of renewable electricity. In 2004, 6.2 million MWh were sold in the voluntary market, of which almost half were to commercial, industrial and non-Federal governmental customers. Altogether, voluntary purchases represented more than 2000 MW of installed capacity. It is not unreasonable to expect that the voluntary market will support more than 7,000 MW of capacity by 2010.³⁶

In Mexico there is currently no green pricing scheme.

2.3 Government Procurement

Government procurement of renewable electricity refers to purchases made by a branch of the Federal or state/provincial government of either renewable electrical energy (such as that delivered by the local utility to a particular building or site), or the purchase of renewable certificates to ‘green’ the electrical energy used by that government agency or site.

Government procurement is most commonly undertaken to replace or ‘green’ the electricity used in government buildings, and for government services such as water pumping and purification, street lighting, etc. Governmental entities often set procurement targets and then issue requests for proposals from renewable electricity suppliers in order to obtain the power or renewable certificates needed at the best price available. Both the U.S. and Canada have various government procurement programs.

2.3.1 Canada

The Canadian government has a renewable electricity procurement target of twenty percent of Federal electricity being procured from renewable energy. It was approved through Cabinet and is expected to be 450,000 MWh/year when complete in 2010. Eligible electricity must be generated and delivered to the province where the purchases are being made. The ownership of the environmental attributes associated with the generation of that electricity must be delivered to the Canadian Government. This Federal procurement is incremental to provincial targets.

³⁶ Based on MWh projections from Holt & Bird, p. 36

The Government of Alberta purchases the equivalent of ninety percent of its electricity consumption from renewables (ramped over a two year period). Toronto has made a twenty-five percent commitment but they have not yet fulfilled it. In general, cities and provinces in Canada are more likely to negotiate a purchase for renewable power and, based on that purchase, then announce their target. One exception is the British Columbia, where the Provincial Government set a fifty percent clean energy target and BC Hydro was given ten years to meet it. The energy must come from renewable resources and meet Ecologo criteria.

Total government purchases of electricity (includes federal, provincial, territorial, municipal, and Crown corporations) are estimated to be 8,000,000 to 15,000,000 MWh/year. However, most electricity is not “procured” per se, since it is provided as part of monopoly utility service. Only the 450,000 MWh/year commitment by the Federal Government is incremental to the provincial targets.

2.3.2 United States

On June 8, 1999, President Clinton issued Executive Order 13123 requiring that federal agencies increase their use of renewable electricity.³⁷ Subsequently, the Secretary of Energy set a goal for federal agencies to source two and a half percent of their electricity from renewable energy by 2005.³⁸ In September 2005 the Department of Energy announced that the goal had been reached and even exceed. A total of 2.4 million MWh of renewable electricity is being used by the federal government on an annual basis in 2005.³⁹ A list of the largest purchasers of renewable electricity in the United States reveals that four of the top nine purchasers of renewable electricity are federal agencies. The four agencies combined buy more than 1,500,000 MWh annually.⁴⁰

New Federal renewable procurement goals were established by the Energy Policy Act of 2005. Federal agencies are directed to obtain three percent of their electricity from renewable sources in fiscal years 2007 through 2009, rising to five percent in fiscal years 2010 through 2012 and seven and a half percent thereafter.⁴¹

A few states, including as Arizona, New York, Maryland, Pennsylvania and New Jersey have instituted similar procurement policies. In 2005 Arizona’s Governor issued an Executive Order requiring “all new state funded-buildings...to derive at least ten percent of their energy from a renewable resource.”⁴² The New York Executive Order mandates that State agencies purchase no less than ten percent of the overall State facility energy requirements from

renewable power sources by 2005. The mandate will increase to twenty percent by 2010.⁴³ Similarly Maryland has an aggressive renewable procurement goal of twenty percent, of which at least ten percent must be derived from wind generation, solar voltaic or solar thermal sources.⁴⁴ Pennsylvania and New Jersey are using ten percent and twelve percent respectively, of state government's electricity usage from renewable sources.^{45 46}

Municipal and state government entities have also been very active in purchasing renewable electricity. As of June 2005, thirty-eight municipal and local governments were purchasing a total of 295,000 MWh/year.⁴⁷

2.3.3 Mexico

There is no federal government initiative to purchase renewable electricity.

2.3.4 NAFTA and Government Procurement

The NAFTA Government Procurement outlined in NAFTA Chapter 10, requires transparency in procurement and bid challenge procedures as well as requiring that suppliers from other NAFTA parties receive treatment “no less favorable” than that provided to local suppliers in procurement. This could be interpreted to mean that government procurement of renewables in all three countries must be open to ‘eligible’ types of facilities or transactions regardless of which country the facility is located in. If that is the case, there may be significant opportunities for cross-border renewables sales where such sales allow the use of renewable certificates.

The North American Green Purchasing Initiative (NAGPI) is an initiative led by the Commission for Environmental Cooperation to advance environmentally preferable government procurement programs in North America. This initiative is assisting all three governments to increase the percentage of renewable electricity procured “to create markets for green products and services from sustainably managed companies, thereby producing tangible economic, social, and environmental benefits.”⁴⁸ The initiative will provide tools and information to encourage institutions, including governments at all levels, universities, hospitals, and private companies, to increase their purchase of renewable electricity, including on-site generation.

⁴⁸ “Promoting Green Purchasing in North America,” http://www.cec.org/files/PDF/ECONOMY/10-6-GreenPurchasingActionPlan_en.pdf, p.1.

2.3.5 Summary of Cumulative Government Procurement

The combined total of Canadian and U.S. Federal government procurement is estimated to be 2,850,000 MWh/year. This will create a demand for roughly 97 MW of capacity. We do not include provincial or state or local government procurements in the summary total because it is assumed that these purchases are not incremental to the demand estimated from provincial targets in the case of Canada, and voluntary purchases, in the case of the U.S.

2.4 Other Demand Drivers

2.4.1 United States

2.4.1.1 Public Benefits Funds

A Public Benefits Fund (PBF) is a fund that is collected through a surcharge on electricity rates or electricity generators and that is used to directly support public purposes related to the electricity sector. There are fourteen U.S. states that offer PBFs; of these six have programs to increase the demand of renewable electricity by providing customer incentives to switch to renewable electricity, providing customer education, offering direct support for renewable electricity marketers, and setting up programs to encourage government and institutional purchases of renewable electricity. Although individually these kinds of programs are not enough to stimulate a dramatic increase in demand for renewable electricity, combined with other state funding and incentives they can cumulatively transform the market in a significant way by creating a sustained demand and raising awareness among potential customers.

2.4.1.2 Shift in the Relative Prices of Renewable Electricity and Fossil Fuels

One of the greatest demand drivers in the U.S. is the reduction in the consumer price gap between renewable electricity and the default electricity offering. Many landfill gas and wind facilities are currently generating electricity at prices below or equal to combined cycle natural gas facilities.⁴⁹ This can be attributed to a number of factors working together: lower costs for wholesale suppliers due to market maturation and economies of scale, economies of scale on the retail side as demand increases, and higher prices for natural gas and other fossil fuels used to generate the default electricity mix.

2.4.1.3 Value of Renewables as a Price Hedge

Unlike some conventional energy resources whose costs vary with the fluctuations of fuel input prices, renewable energy sources typically have fixed and known prices. Some utilities and marketers are structuring renewable electricity offerings to appeal to customers that want a hedge against rising fuel costs. Most renewable electricity products are priced as a premium above the default service electricity offering and/or some require customers to pay

⁴⁹ Hamrin, Jan and Ray Dracker. *Renewable Energy Options & Opportunities - Bay Area Rapid Transit District*, (San Francisco: Center for Resource Solutions, 2004) 24.

a “fuel charge adjustment” fee where fossil fuel cost increases are captured. In either case, when fossil fuel prices increase, then so too does the price for the renewable product. As a departure from this, a handful of utilities have decided to let their renewable electricity customers take advantage of the price stability of renewables. They either price their renewable products independently from the default electricity service, or they have eliminated the “fossil fuel adjustment” surcharge.⁵⁰ Austin Energy, Oklahoma Gas & Electric, Xcel Energy, and Eugene Water and Electric Board are examples of utilities that have used this strategy. Austin Energy’s renewable electricity rate is guaranteed to be stable for ten years, which is an important selling point for energy-intensive corporate customers with long-term concerns about the risks in their power bills.⁵¹

⁵⁰ Bird and Brown, p. 15

⁵¹ With the rising price of natural gas this pricing structure resulted in customers paying less for the renewable energy product than for the standard offer for electric service in two of these regions. For more details on an example of this pricing structure see *World Resources Institute: Corporate Guide to Green Power Markets. Developing “Next Generation” Green Power Products from Corporate Markets in North America. Installment 6.* (Washington, D.C., 2004) 9.

SECTION III. ANALYSIS OF SUPPLY-SIDE DRIVERS

3.1 Self-Supply, On-Site Distributed Generation and Off-Grid Generation

Self-supply refers either to the generation of power on the customer's site, known as on-site distributed generation, or (in the specific case of Mexico) to customers that have off-site generation and pay wheeling services to the distribution grid. The most common forms of on-site distributed generation include co-generation (combined heat and power), emergency generators, photovoltaics (PV), and small biomass or wind generators; off-site projects can be based on wind, hydro or biomass power. All three countries in North America stand to benefit from an increase in the amount of installed MWs of self-supply. This section focuses on the policies and opportunities for increasing the size of this market.

Small-scale, on-site distributed generation has a number of benefits for both the owner and society. Benefits to the owner include potential for lower electricity costs over time, higher service reliability, high power quality, increased energy efficiency, and energy independence. The benefits to society at large include significant environmental benefits from cleaner electricity production, a reduced reliance on the aging grid, peak power demand reduction (seasonal and time of day), avoided distribution and transmission system losses, increasing lifespan of existing generation (reducing the need for additional baseload generation plants), and the ability to provide electrical services to remote rural populations.

3.1.1 Canada

Most policies and programs to encourage self generation in Canada are on the provincial level. They include eliminating the sales tax on small renewable energy equipment, net metering laws such as those in Ontario, British Columbia, and Manitoba and streamlined interconnection standards.

As an example, in August of 2005, the Ontario Minister of Energy issued a directive to the Ontario Power Authority and the Ontario Energy Board asking the two agencies to “co-operate in developing terms and conditions for a standard offer program for small generators embedded in the distribution system that use clean or renewable resources.” The letter encouraged those involved to work on overcoming barriers currently impeding the development of renewable energy and distributed generation. In 2006, Ontario announced a new Standard price contract that is likely to produce 1,000 MW over the next 10 years. The contracts and fixed-price tariff (like a feed-in tariff) are open to all and sets the tariff level at: C\$0.11/kWh for wind, biomass and small hydro; and C\$0.42/kWh for solar photovoltaics.⁵²

⁵² For more information see:

http://www.energy.gov.on.ca/index.cfm?fuseaction=english.news&body=yes&news_id=124; or
<http://www.powerauthority.on.ca/Page.asp?PageID=1224&SiteNodeID=161>

In addition, the Canadian Standards Association is working to establish a national set of standards for distributed generation interconnection. Finally, the federal government is convening a group of experts to discuss the potential impact of widespread proliferation of distributed generation. Some of the topics being discussed include:

- Impact of large scale integration of distributed generation;
- Communication systems for distributed electricity resources;
- Distributed generation regulatory assistance program; and
- Interconnection requirements, standards and guidelines for distributed generation technologies.

Some industrial plants in Canada, especially in the forest products and mining sectors, generate electricity for their own use from biomass or small hydro facilities. According to the Pembina Institute's February 2003 Report, there are also individual consumers using small wind turbines or PV arrays that are not included in any net-metering programs. However, we were not able to collect any data on the size of this sector.

3.1.1.1 Net Metering in Canada

Net metering is a program where any surplus power generated on a customer's site and not immediately consumed is fed into the grid (this happens at certain times of the day and seasons of the year). These small power generators can then take back that excess power at another time thus the consumer is only charged for the net amount of electricity consumed. The utilities allowing net metering at this time are BC Hydro, Hydro One, Manitoba Hydro, Nova Scotia Power, Toronto Hydro, and Maritime Electric (Prince Edward Island). The amounts of power involved are very small compared to other types of renewable programs discussed in this report.

3.1.2 United States

In the U.S., there are four main drivers for the installation of on-site distributed generation: (1) reduced costs due to technology advancements and state and federal incentive programs, (2) favorable net-metering and interconnection policies, (3) market demand for RECs, particularly from solar installations that command a premium in some compliance markets, and (4) customer's belief that renewable distributed generation can help stabilize their costs, particularly as natural gas and electricity prices continue to rise. That is, on-site renewable distributed generation offers an attractive price hedge. Though not currently a major driver, the fact that on-site distributed generation offers reliable power, particularly if storage capability is added, makes it appealing to some industries with high reliability needs.

3.1.2.1 Net-Metering Policies in the U.S.

Most U.S. net-metering policies allow a customer to "store" excess power on the grid such that they are only billed for the net amount of electricity drawn from the grid over a period of time, usually one year. Net metering laws are usually accompanied by other policy features that are designed to encourage the installation of on-site distributed generation units. In

particular, some states offer preferential pricing for power that is delivered to the grid, e.g. crediting the customer with the retail rate for electricity instead of a wholesale generation rate and the avoidance of transmission, distribution, ancillary service fees and stranded costs.

Net metering laws have been enacted in thirty-nine separate states plus the District of Columbia. Though most discussions of net metering focus on solar installations, net metering is also very important for small on-site wind installations. Fuel cells and, in some cases, small cogeneration are also eligible for net metering in about ten states. Other renewable technologies, though often eligible for net metering, are not generally available at the right scale to take advantage of net metering, for example, biodigester or animal waste facilities.⁵³

Net metering alone is an important but insufficient strategy to drive an increase in on-site distributed generation. Most potential on-site renewable generators need financial incentives to help overcome the high technology and administrative costs. Therefore, many states combine net metering policies with other types of distributed generation incentives.

3.1.2.2 Interconnection Policies for On-Site Distributed Generation

The policies controlling grid interconnection requirements can either encourage or discourage small-scale renewable electricity installations. Many utilities have implemented conservative interconnection policies for distributed generation resources because of safety concerns and power quality concerns. Nationally, there is a wide variation among standards for small-scale renewable electricity installations, and even within a single state, policies controlling interconnection can vary between individual utilities. Recently, there have been efforts to simplify, standardize, and expedite the interconnection of renewable electricity systems. Generally, these efforts address issues such as the interconnection application and review processes, timelines and fees, technical and operating requirements, metering and billing options, and other issues. Such policies add certainty to the interconnection process, and they ensure that utility-imposed requirements are not overly conservative. In addition, many states are raising the size of systems that can take advantage of simplified interconnection to anywhere from 1-5 MW. However, despite the progress being made on generalized interconnection protocols and the proliferation of “tool kits” and other resources to help on-site generators navigate the maze of requirements, most distributed electricity developers today still must negotiate interconnection agreements directly with local utilities or regional transmission organizations (RTOs).

FERC has taken some action to remedy this problem by developing an interconnection rule for small generators up to 20 MW in size. The rule, established in May 2005, includes two components: the Small Generator Interconnection Procedures, which describes the technical procedures that utilities and customers shall follow, and the Small Generator Interconnection Agreement, which defines the legal rights and obligations of each party, addresses cost responsibility, lays out milestones for completing the project, and sets forth a process for dispute resolution. Much of the rule is based on pre-existing state policies, and the FERC

⁵³ Database of State Incentives for Renewable Energy, <http://www.dsireusa.org/library/includes/type.cfm?Type=Net&Back=regtab&CurrentPageID=7&Search=TableType>

rule may serve as a model for states newly adopting interconnection standards. Both factors could help improve consistency throughout the nation. Although there has not been enough time to see the impact, advances in standardization at the federal level are very important.

3.1.2.3 State and Federal Incentives for Renewable Distributed Generation

One of the greatest drivers for small scale renewable installation is the availability of financial incentives to help overcome the initial high costs of small renewable systems. The types of state financial incentives vary, and many states have a combination of incentive programs to encourage a variety of installations. The most common type of incentives are buy-down programs (rebates), grants, or low-interest loans. Twenty-four U.S. states have rebate programs for small distributed renewable generation installations or have some sort of loan program.⁵⁴ More recently some state funds have tried different program approaches such as conducting competitive solicitations for on-site projects, building distribution channels to help companies market their product to buyers, providing equity investments in distributed generation manufacturers, purchasing PV systems in bulk and reselling them to buyers, and leasing the on-site technology to potential hosts. With regards to Federal incentives, the EPACT 2005, created a new residential solar tax credit for thirty percent of the qualified PV system expenditures up to a maximum tax credit limitation of \$2,000. Individually, these programs may not make a significant impact, but cumulatively, they are having a large impact on the number of renewable projects deployed, and thus the economies of scale for renewable distributed generation.

3.1.3 Mexico

3.1.3.1 Large-Scale Grid-Connected Self-Supply

A large number of grid-connected self-supply projects are currently operating in Mexico, including several small hydro projects and one landfill methane project. In addition, future renewable electricity projects with a combined capacity of 1,240 MW have obtained a license from the Energy Regulatory Commission (CRE).⁵⁵

The electricity consumers that have developed or seek to develop self-supply projects are driven by their environmental concerns, and by lower and more stable tariffs (hedging against tariff fluctuations). In addition, self-supply projects can benefit from CDM resources (see Section 3.2.3.2) and the accelerated depreciation allowance (see Section 3.2.3.1).

Some of these projects are the result of a commercial agreement between a generator and one or more consumers; who together form a single legal entity by means of a cross-shareholding deal. This allows them to remain in compliance with the LSPEE Act because there is no trading of electricity between them, but rather a mere internal transaction.

⁵⁴ DSIRE, Financial Incentives <http://www.dsireusa.org/summarytables/finacial.cfm?&CurrentPageID=7>.

⁵⁵ Comisión Reguladora de Energía, 2006a.

The current regulatory framework allows the remote self-supply, i.e. projects where the generation and the consumption are located in different locations, and the electricity is transmitted from one to the other by means of a wheeling arrangement with CFE.

In order to favor remote, intermittent renewable electricity self-supply projects (notably wind), CRE issued in January 2006 a revised special interconnection contract⁵⁶ with the following provisions:

- The capacity used for the wheeling charges is defined as the average rather than the maximum capacity.
- The grid acts as an energy bank, allowing the self-supply project to deliver energy at one time and withdraw it at a different time, and to exchange energy between the different time periods (peak, base and intermediate), via a formula based on electricity tariffs.
- The capacity contribution of intermittent electricity generation is assessed as the monthly average generation during one hour per day (peak time) in working days. This capacity is then subtracted from the demand of the consumer(s), in order to determine the applicable demand charges.

In addition, in order to ensure adequate transmission capacity for self-supply projects (especially in the Isthmus of Tehuantepec, where a transmission bottleneck exists), the Energy Regulatory Commission (CRE) has developed an *open season* proposal, aimed at defining the required transmission infrastructure. CFE would build it and then recover the investment by means of wheeling charges.⁵⁷

3.1.3.2 Small-Scale Grid-Connected Self-Supply

According to the LSPEE Act, self-supply under 0.5 MW does not require a permit. However, no regulatory procedures exist to enable the connection to the grid of these small-scale self-suppliers. The Regulatory Commission and the Electrical Research Institute (*Instituto de Investigaciones Eléctricas*, IIE) are currently analyzing ways to address this gap. IIE is carrying out the “Fotored 100” project, aimed at installing 100MW of grid-connected photovoltaic systems in the Northwest of the country.⁵⁸

3.1.3.3 Off-Grid Self-Supply

The off-grid market for renewable electricity is mainly driven by the demand of governmental programs, often with the assistance of bilateral or multilateral cooperation agencies, which have provided capital incentives for the procurement of renewable electricity technologies - mainly photovoltaic and some wind power systems. A combined amount of approximately 50 million dollars has been invested in these programs.⁵⁹

⁵⁶ This new contract substitutes a previous version of September 2001, which did not include the capacity recognition provision, thereby preventing the feasibility of self-supply projects with industrial customers that need to pay demand charges. See: Comisión Reguladora de Energía, 2006b.

⁵⁷ Comisión Reguladora de Energía, 2006c.

⁵⁸ Jorge Huacuz. Personal communication, February 2006.

⁵⁹ Jorge Huacuz. Personal communication, February 2006.

The main ongoing program is the one carried out by the Agricultural Shared-risk Trust Fund (*FIRCO*), with GEF funds (*Fideicomiso de Riesgo Compartido*, 2006). It is geared towards productive rural applications such as water pumping or electric cattle fencing.

In addition, the Energy Ministry (*SENER*) and the governments of four states of Southern Mexico are starting the Integrated Energy Services for Small Communities in Rural Mexico Project (*IESCRM*), with a mix of funds that include a GEF grant, a World Bank loan, and state and federal contributions. The *IESCRM* is aimed at providing electricity from renewable energy sources or hybrid systems to 50,000 households in five years.⁶⁰

3.2 Other Market Supply Drivers

This section includes any other market drivers that were not captured in the three previous subsections including production tax credits, system benefit funds and some air shed issues such as smog and particulate emission policies.

3.2.1 Canada

Canada has several supply-side drivers that encourage renewable energy. They include:

3.2.1.1 Accelerated Capital Cost (Depreciation) Allowance

The accelerated capital cost (depreciation) allowance allows taxpayers an accelerated write-off of up to thirty percent per year of equipment generating electricity from eligible renewables. The federal government currently offers two tax incentives aimed mainly at promoting investment in alternative renewable energy projects: Capital Cost Allowance Class 43.1 in the Income Tax Act, and the Canadian Renewable Conservation Expense.

Established in the 1994 Budget, Class 43.1 allows an accelerated write off of certain equipment that is designed to produce energy in a more efficient way or produce energy from alternative renewable sources. Budget 2005 further accelerates the capital cost allowance rate from thirty percent to fifty percent for certain high efficiency co-generation equipment and the full range of renewable energy generation equipment currently included in Class 43.1. Budget 2005 also extends the range of equipment eligible for Class 43.1 capital cost allowance treatment, and proposes that qualifying start up expenses of projects using these additional technologies be made eligible for treatment as Canadian Renewable and Conservation Expenses. The changes proposed by Budget 2005 represent an estimated \$295 million in enhanced tax incentives.

The Canadian Renewable and Conservation Expense, created in the 1996 Budget, is a category of fully deductible expenditures associated with the start up of renewable electricity (such as wind farms) and energy conservation projects for which at least fifty percent of the

⁶⁰ See http://www.sener.gob.mx/wb2/Sener/Sene_1702_electrificacion_rura

capital costs of the property would be described in Class 43.1. Expenditures under this category are fully deductible, and can be financed using flow through shares. As well, the acquisition and installation of test wind turbines for a project, in cases where the device's primary purpose is to test the site's level of electrical energy production, also qualify for this assistance.

3.2.1.2 Wind Power Production Incentive (WPPI)

The Wind Power Production Incentive (WPPI) provides production incentive payments of 1 cent/kWh, capped at 4,000 MW, for the first ten years of operation to wind power generation facilities over 500 kW in size that are commissioned before April 1, 2010. The WPPI was established through the 2001 Budget, which provided \$260 million to stimulate the development and installation of 1,000 MW of wind power capacity. Budget 2005 provides \$200 million over five years, and a total of \$920 million over fifteen years, to expand the WPPI to 4,000 MW. This program is administered by Natural Resources Canada (NRCan).

3.2.1.3 Renewable Power Production Incentive (RPPI)

The Renewable Power Production Incentive (RPPI) provides an incentive payment of 1 cent/kWh for non-wind renewables that meet Environmental Choice criteria.⁶¹ It is intended to stimulate the installation of up to 1,500 MW of new renewable capacity from emerging sources other than wind, such as small hydro, biomass and landfill gas by 2011 as an initial target. Budget 2005 provides \$97 million over five years starting in 2006-07, and a total of \$886 million over fifteen years, for the RPPI to achieve its target. RPPI falls under the purview of NRCan.

3.2.1.4 Sustainable Energy Science and Technology Strategy

In recognition of the importance of new environmental technologies, the Government of Canada plans to develop, by the end of 2006, a Sustainable Energy Science and Technology Strategy. The Government will contribute \$200 million to the development and implementation of the Strategy. One key objective is to develop a set of medium term research goals around the efficient production and use of renewable energy. A panel of experts has been appointed by the Minister of Natural Resources to initiate the development of this Strategy.

3.2.1.5 The Climate Fund

The Climate Fund has minimum funding of \$1 billion over five years to further stimulate cost effective actions to reduce greenhouse gas emissions. The Fund will purchase, pursuant to a competitive process, credits generated by Canada's Domestic Offsets System.⁶² Examples of the types of projects that could generate these credits include those related to renewable energy and energy efficiency. The Fund will also purchase international Kyoto emission reduction credits that satisfy certain conditions.

⁶¹ <http://www.ns.ec.gc.ca/g7/eco-can.html>.

⁶² More information on the Offsets System and Climate Fund as contained in the Government of Canada's 2005 Project Green can be found at www.climatechange.gc.ca/english/newsroom/2005/plan05_Bgrounder.asp. This site will provide details on the programs as they unfold.

3.2.1.6 Provincial Incentives

Several provinces have their own incentive programs. In the past, Alberta had a Small Power Research and Development Act that resulted in a total of about 108 MW of renewable projects being built. Contracts signed under this act (except for three small wind facilities) remain in force for fifteen facilities.

British Columbia Utilities Commission has resource planning guidelines that include consideration of not just costs and benefits but also other social and environmental externalities. The Provincial Government also introduced a tax exemption for small hydro. In 2003, Ontario filed new regulations that give one hundred percent corporate income tax deduction for facilities used to generate electricity from “clean, alternative or renewable energy sources;” a sales tax rebate on building materials incorporated into such facilities; and a ten year property tax holiday on those same facilities.

All of these incentive programs help to bring down the cost of renewables and hopefully will increase installation and production of power from renewable facilities though not beyond what is included in government targets discussed above.

In total we estimate that Canada’s renewable electricity market is around 31,000,000 MWh/year.⁶³

3.2.1.7 Other Potential Funding Sources

In addition, there are several programs that may provide financing for some emerging renewable technologies though they are not specifically designed for renewables and it is not possible to estimate how much of these funds will support renewables. They include:

- Atlantic Canada Opportunity Agency – Atlantic Innovation Fund – A program designed to strengthen the economy of Atlantic Canada by increasing activity in and to build capacity for innovation and research and development that leads to the commercialization of research and development outputs.
- Sustainable Development Technology Canada – SCTC finances and supports the development and demonstration of clean technologies. It has an investment fund of \$550 million.
- Technology Early Action Measures – TEAM is a technology investment program established under the federal government’s Climate Change Action Plan. TEAM supports late-stage development projects and first-time demonstration projects designed to reduce greenhouse gas emissions. Several federal government departments and agencies operate delivery programs that recommend projects for TEAM funding as do certain regional development agencies.

⁶³ This estimate was derived from the following assumptions. The known provincial targets amount to roughly 8,000 MW of capacity demand. To this number, we added 2000 MW to allow for increases in provincial targets, federal government procurement (which may or may not be captured in the provincial targets) and the possibility that Kyoto implementation will be resolved favorably for renewables. We also assume a 35% capacity factor for renewable projects on average.

3.2.2 United States

3.2.2.1 Production Tax Credit

The U.S. Production Tax Credit or PTC is a tax credit based on annual production of electricity that historically has been available to wind and some biomass resources but was expanded to other renewable resources in the Energy Policy Act of 2005. The PTC has been a critical component of the economic equation for wind developers over the past ten years and has given a major boost to the U.S. wind market and other renewable technologies to a lesser extent. “Production tax credits on wind farms are worth roughly thirty-five percent of the capital cost of a typical wind project. That is the present value of such savings from claiming such credits.”⁶⁴ The PTC, currently valued at 1.9 cents per kWh for the first ten years of operation for wind and “closed loop” biomass projects, 1.9 cents per kWh for the first five years of operation for new geothermal and solar plants, and 0.9 cents per kWh for new “open-loop” biomass.⁶⁵ The PTC has been subject to a series of expirations and retroactive extensions, typically two year periods. This has resulted in a certain market uncertainty that has in turn led to surges of new development as companies struggle to get their project started before the PTC expires. The uncertainty over the longevity of the PTC has diminished potential long-term investment in the renewable industry. The PTC was recently extended through December 2007 as part of the Energy Policy Act of 2005.⁶⁶

3.2.2.2 Public Benefits Funds (PBFs)

Many U.S. state funds have programs that address both supply side and demand side obstacles. Fourteen state PBFs have funds to support renewable electricity. These fourteen PBFs are collecting and spending more than U.S.\$300 million per year on renewable electricity.⁶⁷ This Section will focus on programs established by state funds that help to drive the supply side of the renewable electricity market.

PBFs are used to fund electricity-related public benefit programs such as renewable electricity, research and development, energy efficiency, and low-income customer assistance. PBFs can be collected from a variety of sources, with the most common being a surcharge on end-use electricity rates (i.e., a “wires” or “distribution” charge).

Bollinger et al. (2001) observe that PBF programs for renewable electricity can be categorized into three different models: The Project Development Model uses financial incentives such as production incentives and grants to directly subsidize and stimulate renewable electricity project installation. Most PBFs use this model to some degree. For the most part, these PBFs utilize production incentives, buy-downs/rebates, or other forms of grants as a means of distributing funds, rather than loans or other investment vehicles. Two, the Industry and Infrastructure Development Model uses business development grants, marketing support programs, research and development grants, resource assessments, technical assistance,

⁶⁴ “PTC Most Obvious Benefit in New Energy Bill”. *North American Wind Power*, September 2005.

⁶⁵ *North American Wind Power*, p. 8.

⁶⁶ *North American Wind Power*, p. 1.

⁶⁷ Bollinger et al, 2004. p. 1.

education, and demonstration projects to build industry infrastructure. Three, the Investment Model uses loans, near-equity and equity investments to support renewable energy companies and projects. The PBF programs in Connecticut, Pennsylvania, and Massachusetts have explored this approach.

States have developed a multitude of programs using PBF money. One common approach is to use funds to support large utility-scale renewable electricity projects, such as wind, biomass and geothermal. Support typically comes in the form of cash incentives for electricity production based on a dollar-per-megawatt-hour payment, though other approaches are also used (e.g., direct grants, low-interest loans, etc.). These incentives are often auctioned to those projects that need the lowest incremental amount of support to succeed. In aggregate, through 2004, state PBFs have obligated nearly \$399 million in construction and operational support to support 2,288 MW of such projects; 707 MW of these projects are already on line, with 1,550 MW in the planning stage (See Table 7). The vast majority of these projects are wind power facilities. Although they are not as important as RPS policies in this regard, state renewable electricity funds are beginning to be a significant driver of large project installations.

States have also used PBFs aggressively in order to support distributed generation, especially solar PV. In fact, PBFs have been important to the recent growth in the PV marketplace in the U.S. and have become the nation’s primary driver for PV expansion. A large number of states have developed rebate programs for rooftop, grid-connected solar installations. These rebates range from around \$2/watt to as high as \$6/watt.⁶⁸ In total, state funds are obligating about \$200 million in support of solar PV on an annual basis, with the largest programs operating in California. In California, the state is obligating \$150 million per year in support of solar PV. Approximately 110 MW of new renewable distributed generation has been supported by PBFs; of this amount 83 MW has been supported by California’s PBF.⁶⁹

Table 7. Summary of State Support for Utility-Scale Renewable Projects

Project Location	# of Projects	Original Dollars Obligated (\$)	Current Dollars Obligated (\$)	Capacity Obligated (MW)	Capacity Cancelled (MW)	Capacity Pending (MW)	Capacity On-Line (MW)
CA	60	\$243,573,376	\$193,019,993	1,285.3	30.6	830.1	424.5

*New Hampshire does not currently have a clean energy fund. The single project located in New Hampshire is receiving support from Massachusetts’ clean energy fund.

Source: Clean Energy States Alliance and Lawrence Berkeley Laboratory, September 2004.⁷⁰

Although some success has been gained, political factors will influence the future effectiveness of PBF policies. One problem is that funds are prone to re-appropriation to satisfy short-term governmental budget needs. Also, because of the difficulty in establishing new “taxes” in the U.S., few new PBFs have been created since 2001.

3.2.2.3 Purchasing Tariffs or Feed-In Tariffs

Purchasing tariffs, also know as feed-in tariffs, can be an effective supply-side driver where access to wholesale markets is a problem or where wholesale market prices do not value renewables adequately. The Public Utilities Regulatory Policy Act (PURPA) is one example of a type of feed-in policy that was aggressively implemented in California, and also prominent in Maine, New York, and several other U.S. states. The policy in California and less so in other states was based upon standard long-term contracts and a mandatory fixed-price for some or all of the contract term. This created a market environment in the early to mid 1980s in which renewable energy developers could secure financing for projects because they could sell their output at attractive contract terms (the purchase price of the California contracts began at 4 cents/kWh and increased to 13 cents/kWh by the tenth year of the contracts). As a result of these contracts, a sizable market and manufacturing capacity developed for wind, geothermal, biomass, small hydro and solar technologies in California. Even today, California remains one of the leaders in installed renewable electricity capacity. Other states also brought significant renewable capacity into operation during this period. For example, over forty-five percent of Maine’s electricity supply comes from renewable electricity sources, much of which were developed during the 1980s under PURPA contracts.⁷¹

In general, fixed price feed-in laws have fallen out of favor with U.S. policymakers that increasingly prefer market mechanisms that stimulate competition and minimize cost. However, they are making a comeback in two states, Washington and Minnesota, that offer feed-in tariffs for small scale or community based renewable projects. Washington State passed a law in May 2005 that offers a production incentive for small solar and wind electricity systems. Homes and businesses can earn up to 15 cents per kWh credit for a fixed ten year period, capped at \$2,000 per year. Renewable system owners can earn more if

⁷⁰ Bolinger, Mark et al. “The Impact of State Clean Energy Fund Support for Utility Scale Renewable Energy Projects.” Berkeley Lab and Clean Energy States Alliance, October 2004. p. 3.

⁷¹ Wisner et al, June 2002.

project components are manufactured in-state. In Minnesota, qualifying owners can receive 2.7 cents per kWh net present value over the 20 year life of the power purchase agreement. Although it is too soon to predict a trend towards feed-in tariffs, it is important to note that feed-in tariffs have shown to be an effective supply-side driver of renewable electricity markets.

3.2.2.4 Renewable Energy Bonds

With the passage of the Energy Policy Act of 2005, “clean renewable energy bonds” known as CREBs were added to the Internal Revenue Code for certain electric cooperatives, state and locally-owned utilities, and Indian tribal governments. These bonds represent a tremendous incentive for the construction of new renewable facilities by qualifying electric service providers, particularly since these entities do not pay taxes and therefore cannot take advantage of the PTC. Renewable energy bonds are issued by or on behalf of these electric service providers for the purpose of financing capital expenditure for facilities producing renewable electricity. The benefit is that the issuer is entitled to a tax credit for the amount of the interest of the bond. The bonds must be issued by 2007, but the electric service providers have five years to spend the majority of the proceeds, and they can petition for a longer timeframe. Unlike the two year cycle of the PTC, this longer time horizon provides more certainty and financial stability for potential developers. Another benefit is that the bonds do not limit who owns the facility, who operates the facility, or where the power is sold, so there are real opportunities for private developers to partner with these electric service providers. The Secretary of the Treasury can allocate up to \$800 million in CREBs to qualified projects.⁷²

3.2.2.5 State Tax Incentives

Eleven states have some type of corporate tax incentive for grid-connected, utility-scale renewable electricity facilities. Four states, Iowa, Massachusetts, New Mexico and Oklahoma have production tax incentives, similar to the federal production tax incentive, that pays a fixed amount per kWh of renewable electricity production. Six other states have tax deductions for capital expenditures or equipment. Such incentives range in the amount of the tax benefit, and thus range in their ability to be a driver of new renewable supply.⁷³ Montana has a tax credit for up to thirty-five percent of income earned from the operation of the renewable facility.⁷⁴ In general, while state tax incentives may be helpful for a renewable project, they are generally not drivers for utility-scale large renewable projects for a number of reasons. Project owners may not have much tax liability in that particular state, and state taxes are usually lower than federal taxes, therefore a portion of the tax credit may go unused. Second, most tax incentives are not incremental to the federal PTC, which tends to be much more valuable. This means that the developer can take advantage of the PTC or the state tax credit, but not both.⁷⁵

⁷² *North American Windpower*, p.8.

⁷³ These states include North Dakota, Oregon, Utah, West Virginia, Hawaii, and North Carolina.

3.2.2.6 Other Federal Incentive Programs: Business Investment Tax Credit and Accelerated Depreciation

Other federal incentives for renewable suppliers include business investment tax credit and accelerated depreciation. The business investment tax credit allows businesses that invest in solar or geothermal energy systems to take a thirty percent tax credit to offset the first costs of these systems. This program was authorized under the EPCRA 2005, but will expire in 2007 unless reauthorized. There are also several provisions in Federal Tax Code that promote renewable energy through accelerated depreciation. The “Modified Accelerated Cost Recovery System” sets timelines over which renewable generation equipment can be depreciated. Most such equipment can be depreciated over five years. The Job Creation and Worker Assistance Act of 2000 speeds up the allowed depreciation for some technologies.

3.2.3 Mexico

Two general supply drivers for renewable electricity can be identified in Mexico. The first one is the accelerated depreciation allowance for renewable energy investments, and the second one is the Clean Development Mechanism.

3.2.3.1 Accelerated Depreciation Allowance

The accelerated depreciation allowance, introduced in 2005⁷⁶, allows depreciating the full amount of the investment in “machinery or equipment for the generation of energy from renewable sources”. The depreciation can only be made to the extent that income tax is due. In other words, if the depreciation is larger than the income tax, the taxpayer will need to continue depreciating the investment in the ensuing years.⁷⁷

This allowance benefits in particular the off grid and on-grid self-supply projects. It may be a further driver for the inclusion of renewable electricity projects in CFE’s expansion planning, if and when CFE considers this variable in its planning. Since CFE is not an income tax payer, this allowance does not favor utility-owned projects.

3.2.3.2 Clean Development Mechanism (CDM)

The second driver is the Clean Development Mechanism. The CDM is acting as a driver mainly for the on-grid self-supply projects. With regards to the off-grid projects, CDM is unlikely to become a significant driver, given the negligible scale of the emission reductions. Finally, insofar as the public service projects (included in CFE’s expansion planning) are concerned, since the utility is already considering this income in its planning, CDM is also becoming a driver for these projects.

⁷⁶ Article 40, paragraph XII, of the Income Tax Law (Ley del Impuesto Sobre la Renta, 2005). In order to prevent the misapplication of this allowance, Paragraph XII establishes that the investments need to remain operational during a five-year term.

⁷⁷ Due to this, the accelerated depreciation allowance is particularly beneficial for large firms with other in-country operations. Self-purpose vehicle companies will typically need more than five years to fully depreciate green power investments.

SECTION IV. REGULATORY AND LEGAL OPPORTUNITIES IN MEXICO

A number of proposals for adjusting the current policy framework of the power sector have been made during the last decade in Mexico. Some policy-makers have suggested that the State-owned utilities (CFE and LyFC) should be unbundled (i.e. split into generation, transmission and distribution companies) and/or partially or fully privatized. Others believe that they should remain under the control of the State, but that more opportunities for the private sector should be opened in the generation business - for example by allowing private generators to sell electricity to large industrial consumers. However, an important contingent believes that the State should keep the control of the power sector and recover the terrain it has lost since the 1992 amendments to the LSPEE Act. The future of the Mexican energy sector (including both the oil and the electricity industries) has then become one of the most controversial issues in the Mexican political arena.

4.1 The LAFRE Bill and Article 253-B

Despite this lack of political consensus about the legal framework the Mexican power sector should have, a growing consensus has emerged among a range of stakeholders during the last few years about the need to foster renewable energy. A number of bills have been proposed in Congress, most of which suggest amendments to the LSPEE Act. However, due to political deadlock and the fact that any amendment to the LSPEE Act involves opening a Pandora's Box, a group of members of the Lower Chamber of Congress (*Cámara de Diputados*) brought forward a new law bill - the Renewable Energy Act (LAFRE) - that could co-exist with the former LSPEE Act. This bill was approved by the Lower Chamber in December 2005 (*Cámara de Diputados, 2005a*), and is likely going to be sanctioned by the Senate during the first quarter of 2006.

The LAFRE bill includes among other instruments the creation of a Renewable Energy Fund (FAFRE) that would give financial incentives to renewable energy projects. However, the origin of the resources for the FAFRE Fund would need to be established by means of a separate law instrument, such as the Article 253-B bill.

The Article 253-B bill, proposed in October 2005 at the Lower Chamber of Congress, would create a special levy on fossil fuels, proportional to their carbon contents, i.e. to the carbon dioxide emissions these fuels will cause when burned (*Cámara de Diputados, 2005b*). The levy, equivalent to \$3.30 Mexican pesos (U.S.¢30) per ton of CO₂, would have a negligible impact on fuel prices (0.2 percent in average) and is expected to raise approximately one billion pesos per year that would be directed to the FAFRE Fund.

4.2 The Potential Effects of the LAFRE Bill

The LAFRE bill is mainly focused on the electricity sector, but includes as well instruments for promoting the production of bio-fuels, as well as other applications of renewable energy. If

approved, it would radically change the prospects for the development of renewable electricity in Mexico.

4.2.1 Regulatory Mandate

The LAFRE bill would give CFE an explicit mandate to increase the inclusion of renewable electricity projects within its expansion planning, and, for the sake of regional and industrial development, one part of the new renewable electricity capacity would need to be reserved for small producer (under 30 MW) projects.

CFE would make bids for the procurement of renewable electricity (with simplified procedures in the case of small producer projects). Long-term power purchase agreements would be signed between CFE and independent power producers or small producers, and the tariffs would be fixed (fixed in real terms, i.e. adjustable only according to the inflation and/or foreign currency exchange rates).

In compliance with the LSPEE Act's least cost principle, CFE would pay for renewable electricity at its long-term avoided cost, including:

- The value of the long-term price stability of renewable electricity.
- The value of the reduction of the loss-of-load probability (LOLP), as a proxy for capacity contribution.⁷⁸

Performance-based financial incentives would be available through the FAFRE Fund to cover the gap between CFE's avoided costs and the prices of renewable electricity.⁷⁹

The LAFRE bill establishes a goal of eight percent of electricity generation from renewable energy sources, excluding large hydro (over 30MW), by the end of 2012. This goal includes all project types (utility supply for public service, as well as on-grid and off-grid self-supply), and it can be assumed that all types would have a similar share. This means that renewable electricity would cover eight percent of the public service generation. This assumption involves that, out of the total electricity generation of 328 million MWh/year (328 TWh) foreseen by the current electricity planning (Secretaría de Energía, 2005b) for 2012, renewable electricity would supply 26 million MWh, or 19 million MWh more than the current annual generation of 7 million MWh of renewable electricity.

4.2.2 Voluntary Green Pricing Scheme

The LAFRE bill would establish the creation of voluntary green tariffs and a system for issuing renewable certificates, thereby paving the way for a voluntary green power market.

⁷⁸ The use of the LOLP approach avoids dealing with the concept of capacity, which proves elusive, particularly in the case of intermittent green power technologies, such as wind and solar.

⁷⁹ The LAFRE bill follows the same principles than the LSREDP (see section 2.1.3); the incentives would be given during the first years of project operation.

4.2.3 Large-Scale Grid-Connected Self-Supply

The LAFRE bill does not foresee any financial incentives to self-supply projects. However, it would provide the following benefits to these projects:

- The sale of surplus electricity to the grid would be based on CFE's avoided costs, and these costs would be published on an annual basis.
- The possible contribution of the projects to the grid in terms of providing voltage control or reactive power would be valued and compensated.

4.2.4 Small-Scale Grid-Connected Self-Supply

The LAFRE bill would pave the way for on-site small-scale self-supply schemes, by giving CRE the mandate to establish technical standards and an economic energy exchange procedure (e.g. net-metering) for these projects.

4.2.5 Off-Grid Self-Supply

The LAFRE bill would provide financial incentives to off-grid renewable electricity projects that benefit the poor population in isolated rural areas, by means of renewable energy sources.

In addition to off-grid projects, these incentives would be given as well to grid-connected renewable electricity projects built in remote areas and whose connection to the grid includes distribution lines that enable providing electricity to villages that otherwise would go without electricity service (this instrument intends to build on the potential synergy between rural electrification and the harnessing of local renewable energy sources).

4.2.6 Other Instruments

4.2.6.1 Small Producer Projects

The LAFRE bill would open the way and provide incentives to small producer projects (under 30 MW) that are not included in CFE's expansion planning. The specific mechanics for the access to these incentives remain to be defined, but could adopt the form of a capped feed-in tariff.

4.2.6.2 Access to CDM Resources

The LAFRE bill establishes that the FAFRE Fund would act as an intermediary for CDM resources. This is particularly relevant in the light of the recent decision of the climate negotiations in Montreal, which allows for project activities under a program of activities to be registered as a single Clean Development Mechanism project activity. The FAFRE Fund would then be able to bundle small scale projects. This may be especially relevant for off-grid and small producer projects.

4.2.6.3 Resource Assessment and Research Activities

Finally, the LAFRE bill would offer an additional supply driver to all renewable electricity projects by virtue of the resource assessment, research and development activities it would fund.

4.3 Wind Power Environmental Standard

A further regulatory instrument under development that is set to favor renewable electricity projects is the wind power environmental standard. This standard would ease the environmental licensing process by setting clear guidelines to be followed by wind power projects.

SECTION V. OPPORTUNITIES FOR GROWING THE RENEWABLE ELECTRICITY MARKET

This section discusses the opportunities to expand the green power market in both the supply and demand sides in each of the three countries. We look at specific obstacles to renewable development and offer country-specific recommendations and tri-national recommendations for the Parties to the NAFTA and NAAEC to promote renewable electricity markets in North America.

5.1 Canada⁸⁰

The overall recommendation is the development of a comprehensive renewable electricity vision and strategy for Canada through federal-provincial-territorial cooperation and stakeholder participation. This is in contrast to the present ad-hoc approach. The core components of such a strategy include: financial incentives, integration of renewables into utility resource planning, aggressive customer outreach regarding renewable options, improving the infrastructure for renewable generation, integration of renewable electricity into local planning, and more distributed generation. An overall strategy is needed to coordinate the many different barriers that need addressing in order to maximize the development of renewable electricity in Canada and provide greater confidence for investors.

5.1.1 Financial Incentives

One of the major barriers to non-hydro renewable development in Canada is the price of competing power, two-thirds of which comes from large hydroelectric facilities. This low cost of electricity is good for the Canadian consumer but is a deterrent to the development of currently more expensive renewable technologies.

Another financial barrier that is closely related to the low cost of power is the lack of access to investment capital. Because the price that is likely to be paid for renewables may not cover the project costs, or barely cover the project costs, it is difficult to get financing and the financing that is available may charge a high interest rate due to the perceived financial risks.

Finally, First Nations face special problems because of their remote locations, lack of financial resources and the numbers of low-income families. We believe there may be business models that could be designed to address the specific situations and issues faced by this particular group that might provide incentives for attractive partnerships.

⁸⁰ Many of the recommendations in this section are based on information collected by Pollution Probe and the Summerhill Group in preparation of *A Green Power Vision and Strategy for Canada*, 2004. Also see Pape-Salmon, Andrew, Johathan Dogerom, Carissa Wieler, and Mark Anielski, *Low-Impact Renewable Energy Policy in Canada: Strengths, Gaps and a Path Forward* (Pembina Institute, February 2003) and *Preliminary Framework for a National Renewable Energy Strategy for Canada*, by the Canadian Renewable Energy Alliance, May 2, 2005.

Recommendations

Policies that level the playing field for renewables vis-à-vis traditional generation technologies must be a core component of any strategy to increase Canada's renewable capacity.

- Adjustment of tax policies for development expense write-offs and depreciation of project assets;
- Develop market incentive programs in support of voluntary renewable markets and private sector renewable investments;⁸¹
- Evaluate recently established special funds (see funds listed under Section 3.2.1) that support renewable development to identify gaps and holes (e.g. for First Nations and remote areas, for low-income customers, etc.) and establish supplemental financial support through public benefit fees, pension funds or other financial sources;
- Develop models for First Nations' ownership of renewable electricity facilities including possible joint venture opportunities.

5.1.2 Integration of Renewables into Utility Resource Planning

Non-large hydro renewable electricity is not a key element of Canada's resource supply mix but more of an ad-hoc add-on. Integrating renewable electricity into resource planning and research, development and demonstration expenditures will improve the visibility and support commercialization of these resources. Moreover, the routine integration of renewable electricity into electricity sector planning and commercialization will send a strong signal to the financial community that Canada is serious about long-term implementation of these technologies.

Recommendations

- Encourage an integrated approach to electricity resource planning and procurement that includes consideration of environmental and social externalities. This strategy could incorporate information such as that developed in the CEC project on Calculating Environmental Benefits of Renewable Energy and the North American Green Procurement Initiative;
- Encourage continuous evaluation and updates of national, provincial/territorial and municipal targets to reflect the benefits identified in integrated resource planning and research, development and demonstration activities listed above. National coordination of such efforts would be welcome.

5.1.3 Engaging Canadians

Communicating the benefits and opportunities associated with renewable resource development is a great challenge for all renewable energy advocates. Yet, it is essential to

⁸¹ Note: Canada implemented a Market Incentive Program in 2000 [<http://www2.nrcan.gc.ca/es/erb/prb/English/view.asp?x=457>], however it did not perform as expected.

gain widespread public support for national and provincial/territorial policies and targets if those programs are to be successful. Currently, there is a lack of general information about renewable technologies and lack of information on suppliers and resource availability in Canada. The low participation rate by both residential and commercial sector consumers in renewable electricity programs can be partly attributed to a lack of awareness about the renewable options available to them.⁸²

A successful outreach and engagement strategy generally requires a combination of bottom-up and top-down strategies including community engagement, business education/acquisition programs, various types of market incentives, as well as a comprehensive public education and outreach strategy. Residential consumers have few renewable options except in the two provinces that have restructured their electricity sector (Alberta and Ontario). However, general education of the public concerning the benefits of renewables will help develop support for provincial/territorial green targets as well as building additional support for Canada's climate change initiatives. In addition it is important to support opportunities for Canadians to invest in renewable electricity through such initiatives as community-based projects and cooperatives. Business, industrial and institutional consumers may be excellent targets for purchasing renewable electricity certificates if they understand the potential benefits associated with such purchases.

Recommendations

- Develop comprehensive regional public education and outreach programs using various media resources to inform the public about provincial/territorial and municipal renewable electricity targets, benefits and options available to individual consumers. Resources to support such programs should be developed for use by community leaders, educators, NGOs and the private sector;
- Undertake regional surveys and interpretive polling strategies⁸³ to inform the public about the benefits of renewable electricity and to help suppliers hone their message to attract consumers;
- Undertake a targeted campaign aimed at companies that have a corporate mission statement that is compatible with a renewable purchase. Target multi-national companies that are purchasing renewables/renewable certificates for their facilities in the U.S. and Europe as potential early participants in the program and support their use of "Made with Renewable Electricity" or similar public recognition labels.
- Support the development of community-based or co-operative projects through such mechanisms as standard offer contracts.
- Support First Nations and remote communities' engagement in the renewable market.

5.1.4 Improve the Infrastructure for Renewables

Development of domestic renewable resources always requires some additional expansion of the power grid since renewable resources are often located in a different region from either

⁸² Ibid

⁸³ This approach was taken in Texas with tremendous success.

load centers or traditional central station power plants. In addition, resolving issues associated with integration of intermittent renewable resources (such as wind and solar power), as well as adjusting the operating rules associated with grid access are all important topics to be resolved. In Canada, except cross-border transmission, electricity is under provincial jurisdiction. Close federal-provincial cooperation in this area is essential in order to successfully resolve infrastructure problems.

Recommendations

- Implement a proactive and integrated approach to transmission planning and grid expansion that incorporates provincial/territorial and municipal renewable electricity targets;
- Develop recommendations concerning funding transmission line extensions and upgrades, including reasonable cost sharing by developers, utilities, consumers or governments in public-private partnerships;
- Use regional study groups to evaluate grid integration and coordination issues.⁸⁴
- Develop a Federal/Provincial Best Practices Handbook on Integration of Intermittent and Non-intermittent Renewable Resources into the Electricity Grid based on international experience; use in training programs and adopt in rulemakings.

5.1.5 Integration of Renewable Electricity into Local Planning and Permitting

Planning and permitting bottlenecks both on private and Crown land can slow development and significantly increase costs and risks for renewable developers. Work needs to be done with provincial/state and local government officials to address planning and permitting issues. Because of unique problems facing First Nations, special care should be taken to help with the energy planning for these communities.

Recommendations:

- Develop streamlined models for zoning standards and clarification of land use policies to support renewable electricity targets;
- Develop “one stop shopping” model for the processing of planning applications at provincial levels;
- Develop a Handbook on Best Practices for Planning & Permitting renewable electricity to use in training of local officials and other relevant persons;
- Streamline environmental impact assessments for renewable electricity projects tailored to the needs of specific technologies and harmonized among jurisdictions so that one process offers federal and provincial/territorial approvals;
- Assist First Nations in community energy planning.

⁸⁴ Regional study groups have been used in a number of US states with excellent results in developing consensus plans, approaches and solutions for resolving transmission problems unique to particular geographic areas.

5.1.6 Incorporate More Distributed Generation into the Supply Mix

There are a number of issues associated with net metering and the integration of distributed renewable distributed generation into the overall supply mix that must be addressed in order to bring renewable distributed generation into broader use. Since distributed generation applications are particularly well suited to rural and off-grid applications, we have included recommendations that support First Nation plans for owning, operating and maintaining such systems.

Recommendations:

- Refine net metering programs and interconnection standards where they exist and support their creation where they do not already exist;
- Develop a commonly agreed-upon method for measurement and verification of the output from smaller distributed generation projects so they can be incorporated into renewable certificate program sales;⁸⁵
- Develop a mechanism for issuing and tracking renewable certificates from such projects;
- Incorporate distributed renewable generation into national and provincial targets and support these targets with some type of capital buy-down or other type of incentive program;
- Develop incentive programs for renewable electricity generation in remote communities so it is competitive with subsidized fuels (such as diesel) used in electricity generation.

5.2 United States

5.2.1 Advancing Industrial, Commercial, and Institutional Procurement

Industrial, commercial and institutional procurement, such as universities and local government, has been the major driver of the voluntary market in the U.S. Initiatives to assist these entities in making renewable purchases should be promoted. In a study done by Holt et al (2000) on non-residential demand for renewable electricity, a survey was conducted to assess the barriers to purchasing renewable electricity. Surprisingly, all of the barriers the researchers perceived might be there, such as lack of information, difficulty in having their specific electricity needs met, internal resistance by key decision-makers, fear of increased scrutiny by environmental groups and conflicts with state regulations were relatively insignificant to potential purchasers. Only the extra cost of renewable electricity was a moderate barrier, receiving a ranking of 2.3 out of 5 (1=not at all problematic, 5 =very problematic). The researchers then looked at the motivation of renewable electricity

⁸⁵ The Environmental Choice Program and the Canadian Standards Association are working on a number of related issues. However, it is unclear at this time whether their agenda includes this or the next specific bullet topics. If not, we encourage them to add these items to their list.

purchasers, and the number one reason that companies cited for purchasing renewable electricity is that it is consistent with their organization's values. Other reasons cited in descending order of importance were civic responsibility, employee morale, public image and a desire to cater to environmentally-oriented customers.

Since the time of this survey, several market conditions have changed that might improve the climate for large commercial purchases of renewable electricity or renewable certificates. The price of renewables has dropped in the U.S. and the accessibility of renewable electricity has increased through an increased number of renewable electricity offerings in both competitive and monopoly markets, and through the development of a renewable certificate market. Although renewable certificates make it significantly easier for some non-residential purchasers to buy renewable power, renewable certificates increase the need for adequate verification and tracking systems to provide the necessary validation of renewable certificates ownership and assurances against double-counting. According to the Green-e Program, seventy percent of all non-residential Green-e certified sales were renewable certificate-only sales.⁸⁶ Another factor is the increase in natural gas prices and the impact that will have on electricity rates. Increasingly, companies are viewing fixed price renewable products as a hedge against volatility in the electricity market. Given these factors, a number of recommendations emerge to advance renewable procurement by commercial and institutional customers.

Recommendations

- Help advance the creation of a national certificate tracking network across the U.S. so that large buyers can feel confident of the renewable certificate purchases;⁸⁷
- Expand the deployment of renewable electricity technologies and purchases of electricity or renewable certificates at federal, state and local government sites through the CEC's North American Green Procurement Initiative;
- Increase Federal and state support for and involvement in renewable electricity outreach activities.

5.2.2 Financial Incentives

The two financial incentives that have been making a real impact in terms of new renewable generation in the ground or under development are the PTC and state funds. However, there are many other types of financial programs that could be developed to support more renewable development and to provide more financial certainty for investors. Listed below are recommendations for financial incentives that would greatly boost a U.S. renewable market.

⁸⁶ Certificate-only sales are sales of the renewable certificates without the accompanying electricity. In such a sale, the electricity is sold to another party. Center for Resource Solutions. *Green-e Verification Report Year 2004* (San Francisco: 2004) 4.

⁸⁷ Center for Resource Solutions is starting a new organization, know as the North American Association of Issuing Bodies, designed to help network North American tracking systems and to address compatibility issues.

Recommendations

- Extend the PTC “placed-in-service” period from two years to a timeframe consistent with project development requirements, from 2007 to 2015;
- Develop a federal program that allows the tax credits from the PTC to be traded and transferred, so that their value can be more readily monetized;
- Develop a federal program to allow use of tax-exempt bonds for private developers of renewable electricity projects;
- Increase funds available at the state and Federal level to increase incentives for renewable distributed generation and supporting renewable industry and infrastructure development.

5.2.3 Maintaining Effective State RPS Programs

Well-designed state RPS programs can be a major driver for new renewable development across the U.S. As with all things, the devil is in the details. Recently, a number of state RPS programs have taken a step backwards with regards to RPS implementation policies and have promulgated policies that could hurt the voluntary renewable market. Chief among these is a policy that allows a utility to count green pricing sales towards their state RPS mandate. The problem with allowing this is that it removes the ability for voluntary renewable electricity purchases to be additional to RPS mandates, thus removing an important incentive for renewable electricity buyers.

Another area that is potentially problematic is the interface of RPS programs and other renewable electricity programs with emissions cap and trade programs. As discussed in Section 2.1.2.3, when a pollutant is capped and traded, the only way that emissions are reduced is when an emission allocation is retired. In general, the only way that renewables can claim to reduce capped pollutants is if they are granted allowances or set-asides under the cap. If state, regional or federal carbon regulation follow a similar cap and trade model, it will be to the detriment of renewable marketers who use air quality and carbon benefits as their primary selling point. Likewise, a large proportion of the voluntary commercial buyers are motivated by the carbon reduction benefits of renewables.

Recommendations:

- Support Best Practices policies that discourage state RPS programs from allowing voluntary renewable electricity purchases, either under a green marketing or green pricing scheme, to count towards their RPS target;
- Encourage states to adopt output based cap and trade programs where generators get a pro rata share of allowances or encourage states to provide adequate set-asides for renewables sold in voluntary markets, i.e. using “off-the-top” or other strategies.

5.2.4 Expanding Public Understanding of Renewable Electricity Beyond the Environment

As noted above, some buyers and a few marketers of renewables are increasingly recognizing the value of renewables as a hedge against energy market volatility. This presents a real opportunity in a number of areas. At the utility resource planning level, increasing renewables in a utility's portfolio has real benefits of diversifying the generation portfolio and thus increasing reliability and lowering the risk from fuel volatility. At the individual purchaser's level, on-site renewable distributed generation can also lower the risk of ballooning energy costs, and can improve local reliability, particularly in areas when the aging electrical grid is vulnerable. Overall, an opportunity to change public perception of renewables away from a boutique commodity with appeal only to those with environmental concerns to a much broader audience and potential market should be exploited.

Recommendations:

- Develop materials that promote the benefits of renewables beyond their environmental value;
- Encourage the use of renewables as a financial hedge against volatile fuel prices.

5.3 Mexico

5.3.1 Opportunities in CFE's Expansion Planning Process

The inclusion of new hydro, solar, wind and geothermal power plants in CFE's expansion planning is a very positive signal. Likewise, by considering the flow of CDM resources in its expansion planning process, CFE will be able to internalize this global environmental value of renewable electricity.

If approved, the LAFRE bill would build on the ongoing effort of CFE and strengthen it, in order to further accelerate the inclusion of renewable electricity in the planning process, so as to revert the current decline in its share of total public service electricity supply.

In particular, the LAFRE bill would:

- Give an explicit mandate to CFE to include renewable electricity in its expansion planning, as well as quantitative targets;
- Provide financial incentives for projects that deliver renewable electricity to CFE, thereby compensating the positive externalities;
- Recognize the capacity contribution of intermittent renewable energy sources - notably wind;
- Favor small producer (under 30 MW) projects in two ways: (i) by giving CFE the mandate to include some small projects in its expansion planning; (ii) by providing

incentives to projects not included in CFE's planning (thereby offering a supply driver for these projects).

On the other hand, by means of its technical assistance activities, the LSREDP is also expected to favor the large scale incorporation of renewable electricity by fostering changes in critical departments of CFE (e.g. the dispatch centre CENACE).

Likewise, the project "Action Plan for Removing Barriers to the Full-Scale Implementation of Wind Power in Mexico", funded by the GEF, implemented by the United Nations Development Programme and executed by the Electrical Research Institute (*Instituto de Investigaciones Eléctricas*, IIE) is expected to provide incentives to pilot small-scale wind power projects (that would supply electricity to CFE).

In order to further favor the inclusion of renewable electricity projects in CFE's expansion planning, an additional opportunity lies in the revision of the methodology for determining the fossil fuel price forecasts that the Energy Ministry (SENER) provides to CFE. This is in effect a key factor that influences the whole planning process, and SENER might in particular include risk (price fluctuations) considerations in its methodology.

Recommendations:

- Support the approval of the LAFRE bill;
- Review the methodology for determining the fossil fuel price forecasts.

5.3.2 Opportunities in Green Pricing Schemes

Green pricing represents a significant opportunity to finance renewable electricity projects in Mexico.

The LAFRE bill would enable the creation of voluntary tariffs and a certificate system. If these tariffs were designed by including some sort of long-term stability guarantee (along the lines of what is described in Section 2.4.1.3), they would become even more attractive for potential customers, especially energy-intensive industries.

Recommendation:

- Create green tariffs with a long-term stability guarantee.

5.3.3 Opportunities for Government Procurement of Renewable Electricity

A further opportunity for fostering renewable electricity lies in federal government procurement. It is interesting to note that the federal government is already paying for its own electricity consumption a tariff that is 2.5 times larger than the tariff paid by other consumers in the same conditions, as a result of a decision taken in 2002 to address the

deficit of CFE. It is estimated that this involves an additional payment of approximately 8 billion pesos per year. Despite this decision being temporary, it has not been revoked.

Recommendation:

- Consider redirecting any electricity premiums paid by the federal government toward the purchase of renewable electricity. In particular, the central offices of the Environment and Energy Ministries (SEMARNAT and SENER) might pioneer such an initiative.

5.3.4 Supply-Side Opportunities to Increase Grid-Connected Renewable Electricity in Mexico

The “Action Plan for Removing Barriers to the Full-Scale Implementation of Wind Power in Mexico” (referred above) presents a number of opportunities to foster renewable electricity (with a focus on wind power), by means of a range of technical, policy and project development activities.

The Action Plan has identified the need to develop a special administrative simplification and coordination effort by the federal, state and municipal authorities, in order to facilitate the procurement of the required licenses (land use, archaeology clearances, water use, etc.). In particular, a special effort of the federal, state and municipal governments would be welcome in the Isthmus of Tehuantepec, where an excellent wind resource is available. Such an endeavor would provide all stakeholders with adequate information (e.g. about the financial terms of land-leasing agreements) and to dispel any possible myths about the impacts of wind power.

The LAFRE bill represents some additional opportunities to introduce supply drivers for renewable electricity. It would in particular:

- Provide financial support for the assessment of the potential of renewable energy sources nationwide, thereby overcoming the lack of information barrier for all renewable electricity projects.
- Address public awareness, public participation and social responsibility, thereby contributing to foster social acceptance.

Recommendations:

- Promote administrative simplification and coordination by the federal, state and municipal authorities, in order to facilitate the procurement of the required licenses for new projects;
- Undertake awareness raising activities in resource-rich areas.

5.3.5 Opportunities to Increase On-Grid Self-Supply of Renewable Electricity in Mexico

With the new interconnection contract issued by CRE, new opportunities arise for grid-connected, remote, intermittent renewable energy self-supply projects.

In addition, the LAFRE bill would benefit this market by valuing the contribution of self-supply projects to the grid in terms of voltage control, reactive power, etc.

Recommendation:

- Strengthen the role of development banks (e.g. BANOBRAS) in the provision of guarantees for municipalities in self-supply agreements;

5.3.6 Opportunities to Increase Off-Grid Self-Supply of Renewable Electricity in Mexico

The Integrated Energy Services for Small Communities in Rural Mexico (IESCRM) project will foster at a pilot level off-grid renewable electricity projects in four states, by:

- Offering financial resources and mobilizing existing resources of municipalities and state governments.
- Creating multi-stakeholder committees to ensure program sustainability beyond government administrations at federal, state and local levels.
- Establishing financial schemes such as micro-credit.
- Developing local capacity to ensure appropriate project management, operation and maintenance.
- Fostering the productive uses of energy, in order to ensure poverty reduction impacts.

Recommendation:

- State governments and other institutions might closely follow-up and replicate the experience of the IESCRM project elsewhere, with existing financial resources or with the additional resources that would be available if the LAFRE bill is enacted.

SECTION VI. RECOMMENDATIONS

6.1 Recommendations for the NAAEC Parties

The NAAEC Parties should be commended for their commitment to reduce the impacts of electricity generation and trade on the environment by supporting the increased deployment of renewable electricity technologies. In the previous section, we developed country-specific recommendations for enhancing a market for renewable electricity in each of the three countries. This Section lists specific recommendations for follow-up activities that would support a North American renewable market.

These recommendations will facilitate information sharing among the three countries, and will foster greater cooperation towards encouraging the deployment of more renewable energy across North America. The recommendations below fall into three main categories: (1) informational materials designed to address areas in where lack of information or understanding is a potential barrier to greater renewable deployment in each country, (2) tools, such as databases or guidebooks, that can be used by practitioners in each country to help foster market development, and (3) programs that will promote voluntary purchases of renewable electricity in each country. The core issues that these recommendations address include:

- need for greater understanding of how to integrate renewable generation into the North American power grid, particularly by utilities in each country;
- need for greater understanding of the non-environmental benefits of renewable generation, particularly by utilities and large purchasers of electricity;
- opportunity for an increase in the voluntary purchases of renewable electricity and RECs in all three countries;
- opportunity for the increased deployment of on-site renewable energy technologies.
- opportunity for increased Federal procurement of renewable electricity in each country; and
- opportunity for increased REC trading across North America.

1. Compile best practices for power system dispatch, integration of intermittent resources, and integration of distributed resources. Foster tri-national information sharing on such best practices in a format that is most likely to be effective and useful.

2. Prepare a report that quantifies the financial value and public benefit of renewables as a hedge against fuel costs, a mechanism to increase portfolio diversity. The report would tailor its findings to two main audiences, utility integrated resource planners and large electricity users that may not fully appreciate the price stability of renewables.

3. Help advance programs that will provide recognition to commercial, industrial and institutional purchasers of renewable electricity, such as the EPA Green Power Partnership or

“Made with Renewables” or similar product labeling initiatives. Support tri-national information sharing on how to best develop a buyers recognition program.

4. Develop case studies of the most successful programs for encouraging companies to either buy renewable electricity install on-site renewable generation, or become equity owners in utility-scale generation projects. Identify the most compelling motivational factors for these electricity users. Investigate opportunities for enhancing, expanding or replicating such programs in relevant markets.

5. Help advance the development and expansion of a North American market for RECs. Help advance the development of compatible standards for REC integrity and initiatives to prevent double counting of RECs used in voluntary and mandatory markets.

6. Help advance Federal government renewable electricity procurement initiatives in each of the three countries.

7. Develop a compendium of policies, examples, best-practices, and “how-to guides” for off-grid distributed renewable generation that would provide practical guidance for small groups, e.g. indigenous populations, to select, finance, and install renewable distributed generation.

8. Help advance work to update and expand user functionality of the North American Renewable Energy Directory.

9. Prepare a report on the key market demand and supply drivers for non electrical applications of renewable energy technologies.

10. Prepare a report focusing on the development, deployment and market drivers for renewable energy technologies.

11. Increase international cross-border trading of renewables between the three countries on short- and long-term markets.

To implement these recommendations, we recommend establishing two sub-groups: one that would deal with technology and technical issues and another sub-group that would address issues related to the creation of a North American market for renewable electricity and RECs from both utility-scale generation and on-site generation. Both groups should work on a consensus basis. Their first tasks would be to capture in a few words the goal to be achieved and to have all participants agree to it before they commit themselves fully to the program. The next step would be to formulate a work plan and the related deliverables, along with a detailed schedule.

Defining the work to be done by each sub-group in this manner would allow their respective members to concentrate on key issues, leaving aside all fruitless debate. The sub-groups could then formulate recommendations that focus directly on the emergence of a large, prosperous and diversified trading zone for renewable electricity and RECs in North America

with a sufficient critical mass that would make it possible, in the long run, to offset large volumes of less environmentally friendly power generation.

LSPEE	<i>Ley del Servicio Público de Energía Eléctrica</i> (Public Electricity Service Act, Mexico)
LSREDP	Large-Scale Renewable Energy Development Project

LyFC	<i>Luz y Fuerza del Centro</i> (Light and Power of the Center, Mexican State-owned utility)
MW	Megawatt (unit of power)
MWh	Megawatt-hour (unit of energy)
NAAIB	North American Association of Issuing Bodies
NO _x	Nitrogen Oxides
PBF	Public Benefits Fund
PEMEX	<i>Petróleos Mexicanos</i> (National Mexican Oil Company)
PURPA	Public Utility Regulatory Policy Act
QF	Qualifying Facility
REC	Renewable Energy Certificate (generic)
RPS	Renewable Portfolio Standard
RTO	Regional Transmission Organization
SENER	<i>Secretaría de Energía</i> (Energy Ministry, Mexico)
SO _x	Sulfur Dioxide
TRC	Tradable Renewable Certificate
WPPI	Wind Power Production Incentive
RPPI	Renewable Power Production Incentive
REDI	Renewable Energy Deployment Incentive
